

Technical report: Adaptivity and optimality of the monotone least squares estimator for four different models.

Eric Cator
Delft University of Technology

September 11, 2009

Abstract

In this paper we will consider the estimation of a monotone regression (or density) function in a fixed point by the least squares (Grenander) estimator. We will show that this estimator is fully adaptive, in the sense that the attained rate is given by a functional relation using the underlying function f_0 , and not by some smoothness parameter, and that this rate is optimal when considering the class of all monotone functions, in the sense that there exists a sequence of alternative monotone functions f_1 , such that no other estimator can attain a better rate for both f_0 and f_1 . We also show that under mild conditions the estimator attains the same rate in L^q sense, and we give general conditions for which we can calculate a (non-standard) limiting distribution for the estimator.

1 Introduction and results

There exists an extensive literature on the problem of estimating a monotone increasing regression function or monotone decreasing density. We will consider the NPMLE or Grenander estimator for a monotone density, see [GRENANDER (1956)], and the least squares estimator for a monotone regression function. Prakasa Rao obtained the rate and the limiting distribution for the Grenander estimator in a fixed point in [PRAKASA RAO (1969)], and in [BRUNK (1970)] a similar result was obtained for the least squares estimator. Results for global measures of convergence were obtained in [GROENEBOOM, HOOGHIEBMA, LOPUHAÄ (1999)] and [KULIKOV, LOPUHAÄ (2005)] for the density case, and in [DUROT (2002)] for the regression case. A unified approach that incorporates some other well known monotone estimators is given in [DUROT (2007)]. A common problem with these results is that they can only be proved under quite strong conditions, in which case there exist other non-isotonic estimators with faster rates.

Another approach, which addresses adaptivity, can be found in [KANG, LOW (2002)]. Here the authors define an estimation procedure for $f_0(0)$, where f_0 is a monotone regression function in the white noise model, that is rate-adaptive in a minimax sense, for any L_q ($q \geq 1$) loss-function, with respect to a Lipschitz parameter α . A serious drawback of this procedure compared to the estimator we consider, is that it does not, in general, give a monotone function as an estimate, when the procedure is applied to an interval of fixed points. Furthermore, the rate is described in terms of a Lipschitz parameter, not allowing for fast rates when the function f_0 has derivative 0 in 0, nor for slow rates when the function is not Lipschitz for any parameter value, nor for rates that

cannot be described by the Lipschitz parameter alone (think of logarithmic corrections).

In this paper we will derive the rate at which the least squares estimator (or Grenander estimator) estimates $f_0(0)$, for a completely general monotone function f_0 that is continuous in 0, for four different models: the white noise model, measurements on a grid (not necessarily with normal errors), measurements on random design points and a sample from a decreasing density. This rate is defined in terms of the probabilistic error. This means that if we for example consider the white noise model

$$Y(t) = \int_0^t f_0(s) ds + \frac{1}{\sqrt{n}} W(t),$$

for $t \in [-1, 1]$, and we fix some $0 < \alpha < 1$, we get a rate a_n that satisfies

$$\mathbb{P}(|\hat{f}(0) - f_0(0)| \geq a_n) \leq \alpha.$$

This way of determining a rate is essential if we wish to get the full generality of our results, as was also observed in [CAI, LOW (2006)]. Our rate is defined in terms of a functional relation involving the function f_0 . It turns out that the rate is similar for all four models, and to define it in the white noise case, we assume without loss of generality that $f_0(0) = 0$ and define

$$F_0(t) = \int_0^t f_0(s) ds.$$

Note that this function is convex, and due to the continuity of f_0 in 0 (without which, we cannot estimate $f_0(0)$ consistently), we have that $F_0'(0) = 0$. Then we fix $C > 0$ and we define $a, r_a > 0$ and $b, r_b > 0$ depending on n such that

$$F_0(r_a) = ar_a, \quad F_0(-r_b) = br_b \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = Cn^{-1/2}. \quad (1.1)$$

Note that except for the simpler case where $F_0(-1) = 0$ or $F_0(1) = 0$, these equations always have a unique solution for n large enough. Define the functions ψ_l and ψ_r by

$$\psi_r(s) = \limsup_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} \quad \text{and} \quad \psi_l(s) = \limsup_{t \uparrow 0} \frac{F_0(st)}{F_0(t)} \quad (s \in [0, 1]). \quad (1.2)$$

If $F_0(t) = 0$ for some $t > 0$, we define $\psi_r(s) = 0$ for $s \in [0, 1)$ and $\psi_r(1) = 1$, and likewise for ψ_l . It is not hard to show that ψ_r and ψ_l are convex increasing functions, such that $0 \leq \psi_r(s), \psi_l(s) \leq s$. We will show the following theorem:

Theorem 1.1 *With the notations as above, we have that*

$$\begin{aligned} \limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \geq a) &\leq \mathbb{P}\left(\inf_{s \leq 0} W(s) - Cs \leq \inf_{0 \leq s \leq 1} W(s) - C(s - \psi_r(s))\right), \\ \limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \leq -b) &\leq \mathbb{P}\left(\inf_{s \leq 0} W(s) - Cs \leq \inf_{0 \leq s \leq 1} W(s) - C(s - \psi_l(s))\right). \end{aligned}$$

The actual rate is therefore given by $\max(a, b)$, since the probability on the right hand side always goes to zero as $C \rightarrow \infty$, and when ψ_r or ψ_l differs from the identity function, the respective

probability goes to zero exponentially fast in C . This will also allow us to establish L^q convergence of the estimator in the following sense. Define the increasing function

$$G_0(t) = F_0(t)/t.$$

If $F_0(1) > 0$, it is possible to define G_0^{-1} as a strictly increasing continuous function on $[0, F_0(1)]$. Choose a_δ small enough and define

$$H_0(a) = \begin{cases} a\sqrt{G_0^{-1}(a)} & \text{if } |a| \leq a_\delta \\ a - \text{sgn}(a)a_\delta + H_0(\text{sgn}(a)a_\delta) & \text{if } |a| > a_\delta. \end{cases}$$

The connection with the rate equations (1.1) is given by $G_0^{-1}(a) = r_a$ and $H_0(a) = Cn^{-1/2}$, for $0 < a < a_\delta$. We will show the following theorem:

Theorem 1.2 *Suppose $\psi_r(s) < s$ for some $s \in (0, 1)$. Let $\chi : [0, \infty) \rightarrow [0, \infty)$ be such that for some constants $K > 0$ and $m \geq 1$*

$$\begin{aligned} \chi(a) &\leq H_0(a) & \text{for } a \leq a_\delta \\ \chi(a) &\leq KH_0(a)^m & \text{for } a > a_\delta. \end{aligned}$$

Then there exists constants $L_1, L_2, \gamma, n_0 > 0$ such that for all $n \geq n_0$ and $C > 0$

$$\mathbb{P}(n^{-1/2}\chi(\hat{f}(0)_+) \geq C) \leq L_1 e^{-L_2 C^\gamma}.$$

We can use this to show that if there exists $\alpha, M > 0$ such that $f_0(x) \leq Mx^\alpha$ for positive x in a neighborhood of 0, then for any $q > 0$

$$\limsup_{n \rightarrow \infty} n^{\frac{\alpha}{2\alpha+1}} \mathbb{E}((\hat{f}(0) - f_0(0))_+^q) < +\infty.$$

Here we use the notation $x_+ = \max(0, x)$. Note that controlling the behavior of f_0 to the right of 0, only controls the “overshoot” of the estimator.

We will also determine weak regularity conditions for F_0 , such that we can determine the limiting distribution of $\hat{f}(0)$. Suppose

$$\lim_{n \rightarrow \infty} \frac{r_a}{r_b} = \gamma \in [0, \infty).$$

This says that the rates to the left and to the right of 0 are well behaved with respect to each other, which is a natural condition for a limiting distribution to exist. Furthermore, suppose F_0 is regularly varying near 0: there exists $\alpha > 1$, such that for all $s > 0$

$$\lim_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} = s^\alpha.$$

This says that F_0 scales properly near 0, which is another natural condition: we don’t want different behavior of F_0 for different scales. We will prove the following theorem:

Theorem 1.3 Let W_s ($s \in \mathbb{R}$) denote twosided standard Brownian motion, and define the process

$$X(s) = \begin{cases} W_s + s^\alpha & \text{for } s \geq 0, \\ W_s + \gamma^{\alpha-1/2}|s|^\alpha & \text{for } s \leq 0, \end{cases}$$

and the process $\hat{X}(s)$ as the greatest convex minorant of X . With the conditions given above, we have that

$$\frac{\hat{f}(0)_+}{H_0^{-1}(n^{-1/2})} \xrightarrow{d} \frac{d\hat{X}}{ds}(0)_+ \quad \text{and} \quad \frac{\hat{f}(0)_-}{-H_0^{-1}(-n^{-1/2})} \xrightarrow{d} \frac{d\hat{X}}{ds}(0)_-.$$

Finally we will show that the rate for $\hat{f}(0)$ is local asymptotic minimax:

Theorem 1.4 Choose two significance levels $\alpha \in (0, 1)$ and $\beta \in (0, 1/2)$. There exist $\eta > 0$, such that for all n large enough, we can find a monotone function f_1 (close to f_0), and we can find a rate γ_n with

$$\limsup_{n \rightarrow \infty} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{f}(0) - f_i(0)| \geq \gamma_n \right) \leq \alpha$$

and

$$\liminf_{n \rightarrow \infty} \inf_{\hat{\theta}} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq \eta \cdot \gamma_n \right) > \beta,$$

where $\hat{\theta}(Y)$ is any estimator of $f(0)$ based on the data Y .

This says that $\hat{f}(0)$ attains a certain rate γ_n for both f_0 and the sequence of alternatives f_1 (of course we take γ_n a constant times $\max(a, b)$), and no other estimator can do significantly better for both f_0 and f_1 simultaneously. This way of describing optimality was inspired by a talk in Oberwolfach, given by Tony Cai and Mark Low, although their concept looked at the L_q -risk and it did not require that $\hat{f}(0)$ estimate f_1 with the same rate.

We would like to give some feel for Equations (1.1). Suppose f_0 is Lipschitz continuous in 0 with parameter $\alpha > 0$, so for x in a neighbourhood of 0, we have (remember that $f_0(0) = 0$)

$$|f_0(x)| \lesssim |x|^\alpha.$$

Here, $g(x) \lesssim h(x)$ denotes there exists a constant $M > 0$ such that $g(x) \leq Mh(x)$ for all relevant x . Then $F_0(x) \lesssim |x|^{\alpha+1}$, so (1.1) gives us

$$ar_a \lesssim r_a^{\alpha+1}.$$

This means that $r_a^{-1} \lesssim a^{-1/\alpha}$. Together with the second equality for a in (1.1)

$$a \lesssim r_a^{-1/2} n^{-1/2},$$

this leads to

$$a \lesssim n^{-\frac{\alpha}{2\alpha+1}}.$$

For b we can derive the same bound. This corresponds to the rate found in [KANG, LOW (2002)]. Another interesting case is when $\lim_{a \rightarrow 0} r_a = r_0 > 0$. This means that f_0 is flat to the right of 0, on the interval $[0, r_0)$. Then

$$a \lesssim r_0^{-1/2} n^{-1/2},$$

so this corresponds to a parametric rate.

The rest of the paper is organized as follows: Section 2 considers the functions ψ_r and ψ_l . Section 3 deals with the white noise model, for which we will prove all the above results. Sections 4, 5 and 6 each deal with one of the other three models we will consider, but we will only formulate and prove the corresponding theorems of Theorem 1.1, giving the rate, and Theorem 1.4, showing the optimality of the rate. The other theorems, concerning the L^q convergence and the limiting distribution, require some weak technical conditions, but the ideas are the same as for the white noise model, and are not worked out in this paper.

2 The functions ψ_r and ψ_l

In this section we will take a closer look to the functions ψ_r and ψ_l defined in (1.2) in the Introduction. We will concentrate on ψ_r , since completely analogous statements will hold for ψ_l . Since the function $s \mapsto F_0(st)$ is convex and increasing for all $t > 0$, we get that $\psi_r(s)$ is also an increasing and convex function on $[0, 1]$ (this is true for the lim sup of convex functions, not necessarily for the lim inf). Furthermore, we clearly have that $\psi_r(0) = 0$ and $\psi_r(1) = 1$. Finally, since F_0 is convex, we know that for $s \in [0, 1]$,

$$F_0(st) \leq sF_0(t) + (1-s)F_0(0) = sF_0(t).$$

This shows that for any F_0 we have that $\psi_r(s) \leq s$.

Lemma 2.1 *For each $\tau \in [0, 1)$, there exists a positive continuous increasing function η with*

$$F_0(t) = 0 \Rightarrow \eta(t) = 0 \quad (\forall t \in [0, 1]),$$

such that for all $t \in (0, 1]$ and for all $s \in [0, \tau]$

$$F_0(st) \leq (\psi_r(s) + \eta(t))F_0(t).$$

Proof: Suppose $F_0(t) > 0$ for all $t > 0$. Define the auxiliary functions

$$G_t(s) = \sup_{u \leq t} \frac{F_0(su)}{F_0(u)}.$$

These functions are all convex and they decrease pointwise to ψ_r on $[0, 1]$. Since $G_t(0) = 0$ for all $t > 0$, we conclude that G_t converges uniformly to ψ_r on $[0, \tau]$. Define

$$\eta(0) = 0 \quad \text{and} \quad \eta(t) = \sup_{s \in [0, \tau]} |\psi_r(s) - G_t(s)| \quad (t \in (0, 1])$$

and note that

$$\frac{F_0(st)}{F_0(t)} \leq G_t(s) \leq \psi_r(s) + \eta(t),$$

to conclude the statement of the lemma (note that ψ_r is continuous on $[0, \tau]$, so η is indeed a continuous increasing function). Now suppose that $F_0(t) = 0$ for some $t > 0$. We defined $\psi_r(s) = 0$ for $s \in [0, 1)$ in this case. Define

$$r_0 = \sup\{t \in [0, 1] : F_0(t) = 0\}.$$

If $r_0 = 1$, then the statement of the lemma holds with $\eta = 0$. Suppose $r_0 < 1$. Since $s \leq \tau$, we have for each $t \leq r_0/\tau$, $F_0(st) = 0$. Define $\eta(t) = 0$ for $t \in [0, r_0]$, $\eta(t) = 1$ for $t \in [r_0/\tau, 1]$, and continuous in between, and the statement of the lemma holds trivially. $\square$

Let $\{W_s : s \in \mathbb{R}\}$ be a two-sided Brownian motion. We will encounter the probabilities in the next lemma throughout the rest of the paper.

Lemma 2.2 *For any F_0 we have that*

$$\mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 \leq s \leq 1} W_s - C(s - \psi_r(s))\right) \leq \frac{1}{\sqrt{2\pi}C}.$$

If there exists $s \in (0, 1)$ such that $\psi_r(s) < s$, then there exist $\tau \in (0, 1)$ and $\rho \in (0, 1]$ such that

$$\mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 \leq s \leq 1} W_s - C(s - \psi_r(s))\right) \leq \sqrt{\frac{2}{\pi\tau}} \frac{1}{C\rho(2-\rho)} e^{-C^2\tau\rho^2/2}.$$

Proof: First note that the left-hand side and the right-hand side of two-sided Brownian motion are independent. It is therefore enough to consider the two sides within the probability separately. It is well known that

$$\mathbb{P}(\inf_{s \leq 0} W_s - Cs \leq -v) = \mathbb{P}(\sup_{s \geq 0} W_s - Cs \geq v) = e^{-2Cv}.$$

This follows from the hitting time of a linear boundary. Since for all F_0 we have that $\psi_r(s) \leq s$, we also need that

$$\mathbb{P}(\inf_{0 \leq s \leq 1} W_s \leq -w) = \mathbb{P}(\sup_{0 \leq s \leq 1} W_s \geq w) = 2(1 - \Phi(w)),$$

where Φ is the distribution function of the standard normal distribution. We get

$$\begin{aligned} \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 \leq s \leq 1} W_s - C(s - \psi_r(s))\right) &\leq \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 \leq s \leq 1} W_s\right) \\ &= \frac{2}{\sqrt{2\pi}} \int_0^\infty e^{-2Cw} e^{-\frac{1}{2}w^2} dw \\ &= 2e^{2C^2}(1 - \Phi(2C)) \\ &\leq \frac{1}{\sqrt{2\pi}C}. \end{aligned}$$

Now suppose that for some $s \in (0, 1)$, $\psi_r(s) < s$. Since ψ_r is convex, $\psi_r(0) = 0$ and $\psi_r(1) = 1$, this implies that for any $\tau \in (0, 1)$ and any $s \in (0, \tau]$, $\psi_r(s) \leq s\psi_r(\tau)/\tau < s$. Choose $\tau \in (0, 1)$ and define $\rho = 1 - \psi_r(\tau)/\tau > 0$. Then

$$\forall s \in [0, \tau] : s - \psi_r(s) \geq \rho s.$$

Now use that

$$\begin{aligned} \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 \leq s \leq 1} W_s - C(s - \psi_r(s))\right) &\leq \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 \leq s \leq \tau} W_s - C\rho s\right) \\ &\leq \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq W_\tau - C\rho\tau\right). \end{aligned}$$

This last probability we can calculate exactly:

$$\begin{aligned}
\mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq W_\tau - C\rho\tau\right) &= 1 - \Phi(C\sqrt{\tau}\rho) + \frac{1}{\sqrt{2\pi\tau}} \int_0^\infty e^{-2Cv} e^{-\frac{(v-C\tau\rho)^2}{2\tau}} dv \\
&= 1 - \Phi(C\sqrt{\tau}\rho) + (1 - \Phi(C\sqrt{\tau}(2-\rho))) e^{C^2\tau(2-\rho)^2/2} e^{-C^2\tau\rho^2/2} \\
&\leq \sqrt{\frac{2}{\pi\tau}} \frac{1}{C\rho(2-\rho)} e^{-C^2\tau\rho^2/2}.
\end{aligned} \tag{2.1}$$

□

We will now consider the case where $F_0(st)/F_0(t)$ actually has a limit. This is comparable to saying that F_0 is a regularly varying function in 0, but we have the extra information that F_0 is convex.

Lemma 2.3 *Suppose for each $s \in (0, 1]$ we have $F_0(s) > 0$ and*

$$\lim_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} = \psi_r(s).$$

Then either $\psi_r(s) = 0$ on $[0, 1)$, or $\psi_r(s) = s^\alpha$, for some $\alpha \geq 1$. In the latter case, we have that for each $\tau > 0$ (also for $\tau \geq 1$)

$$\sup_{s \in [0, \tau]} \left(\frac{F_0(st)}{F_0(t)} - s^\alpha \right) \xrightarrow{t \downarrow 0} 0.$$

Proof: Suppose $0 \leq u \leq s \leq 1$. Then

$$\psi_r(us) = \lim_{t \downarrow 0} \frac{F_0(ust)}{F_0(t)} = \lim_{t \downarrow 0} \frac{F_0(ust)}{F_0(st)} \frac{F_0(st)}{F_0(t)} = \psi_r(u)\psi_r(s).$$

Since ψ_r is continuous and convex on $[0, 1)$ and $\psi_r(0) = 0$, we conclude that either $\psi_r(s) = 0$ on $[0, 1)$ or $\psi_r(s) = s^\alpha$ with $\alpha \geq 1$. In this last case, choose $s > 1$. Then

$$\lim_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} = \left(\lim_{t \downarrow 0} \frac{F_0(t)}{F_0(st)} \right)^{-1} = \left(\lim_{t \downarrow 0} \frac{F_0(s^{-1}t)}{F_0(t)} \right)^{-1} = s^\alpha.$$

The family of convex functions $\{s \mapsto F_0(st)/F_0(t)\}$ converges pointwise to the convex function $s \mapsto s^\alpha$, and all functions are 0 in 0, so the convergence is actually uniform on compact subsets of $[0, \infty)$. □

3 The monotone LS-estimator in white noise

We will work in the white noise model, so our data $Y(t)$ satisfies

$$dY(t) = f_0(t)dt + \varepsilon dW(t),$$

where f_0 is a monotone L^2 -function on $[-1, 1]$ and $W(t)$ is standard two-sided Brownian motion. As usual, the parameter ε should be compared to $n^{-1/2}$. We wish to study the least squares estimator, but in fact we will define for a realization of $W(t)$,

$$Y(t) = \int_0^t f_0(t)dt + \varepsilon W(t),$$

and the convex function

$$\hat{F}(t) = \sup\{\phi(t) : \phi \text{ affine and } \forall s \in [-1, 1] : \phi(s) \leq Y(s)\}.$$

So $\hat{F}$ is the greatest convex minorant of Y . Now we define the estimator $\hat{f}$ as the left-derivative of the convex function $\hat{F}$, so for $t \in (-1, 1)$

$$\hat{f}(t) = \lim_{h \downarrow 0} \frac{\hat{F}(t) - \hat{F}(t-h)}{h}.$$

This is a monotone function and can be seen as a limit of least squares estimators over the class of monotone functions absolutely bounded by M , as $M \rightarrow \infty$.

We will assume without loss of generality that $f_0(0) = 0$. Furthermore, to ensure that our estimator $\hat{f}(0)$ is consistent as $\varepsilon \rightarrow 0$, we assume that f_0 is continuous in 0. We are interested in the probability of the event $\{\hat{f}(0) \geq a\}$, for $a > 0$. Define

$$F_0(t) = \int_0^t f_0(s) ds.$$

Fix $C > 0$ not depending on ε , and choose $a, b > 0$ and $r_a, r_b > 0$ such that

$$F_0(r_a) = ar_a, \quad F_0(-r_b) = br_b \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = C\varepsilon. \quad (3.1)$$

Since F_0 is convex and continuous, and f_0 is continuous in 0, this can always be done if $F_0(1) > 0$ and $F_0(-1) > 0$, simply by choosing ε small enough. We will consider the special (and simpler) case $f_0(t) = 0$ for all $t > 0$ (or for all $t < 0$) separately.

Theorem 3.1 *With the notations as above, we have that*

$$\limsup_{\varepsilon \downarrow 0} \mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 < s \leq 1} W_s - C(s - \psi_r(s))\right)$$

and

$$\limsup_{\varepsilon \downarrow 0} \mathbb{P}(\hat{f}(0) \leq -b) \leq \mathbb{P}\left(\inf_{s \leq 0} W_s - Cs \leq \inf_{0 < s \leq 1} W_s - C(s - \psi_l(s))\right).$$

Since both probabilities tend to zero when $C \rightarrow \infty$, it follows that Equations (3.1) determine an upper bound for the rate of convergence of $\hat{f}(0)$.

Proof: We will only show the result for a ; the proof for b is completely similar. Note that we have the following “switch relation” for the greatest convex minorant:

$$\{\hat{f}(0) \geq a\} = \left\{ \inf_{-1 \leq t \leq 0} (\varepsilon W_t + F_0(t) - at) \leq \inf_{0 < t \leq 1} (\varepsilon W_t + F_0(t) - at) \right\}. \quad (3.2)$$

We can rewrite (3.2) as follows:

$$\begin{aligned} \{\hat{f}(0) \geq a\} &= \left\{ \inf_{-r_a^{-1} \leq s \leq 0} (r_a^{-1/2} W_{r_a s} + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - \varepsilon^{-1} r_a^{1/2} a s) \leq \right. \\ &\quad \left. \inf_{0 < s \leq r_a^{-1}} (r_a^{-1/2} W_{r_a s} + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - \varepsilon^{-1} r_a^{1/2} a s) \right\}. \end{aligned} \quad (3.3)$$

Define

$$\tilde{W}_s = r_a^{-1/2} W_{r_a s}.$$

Clearly, $\tilde{W}_s$ is also a two-sided Brownian motion. Now we can use Lemma 2.1: for any $\tau \in (0, 1)$ there exists a positive continuous function η with $F_0(t) = 0 \Rightarrow \eta(t) = 0$, such that

$$\inf_{0 < s \leq r_a^{-1}} (r_a^{-1/2} W_{r_a s} + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - \varepsilon^{-1} r_a^{1/2} a s) \leq \inf_{0 < s \leq \tau} \tilde{W}_s - C(s - \psi_r(s)) + C\eta(r_a).$$

Now remark that for $s < 0$, $F_0(s) \geq 0$, so that

$$\inf_{-r_a^{-1} \leq s \leq 0} (r_a^{-1/2} W_{r_a s} + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - C s) \geq \inf_{s \leq 0} (\tilde{W}_s - C s).$$

In view of (3.3), we have shown that

$$\mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s \leq 0} (\tilde{W}_s - C s) \leq \inf_{0 < s \leq \tau} \tilde{W}_s - C(s - \psi_r(s)) + C\eta(r_a)\right). \quad (3.4)$$

Define $r_0 = \lim_{a \downarrow 0} r_a$. Since we always have that $F_0(r_0) = 0$, we conclude that $\lim_{a \downarrow 0} \eta(r_a) = 0$, so

$$\limsup_{\varepsilon \downarrow 0} \mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s \leq 0} (\tilde{W}_s - C s) \leq \inf_{0 < s \leq \tau} \tilde{W}_s - C(s - \psi_r(s))\right).$$

Since this is true for all $\tau \in (0, 1)$, and since ψ_r is increasing on $[0, 1]$, we conclude that

$$\limsup_{\varepsilon \downarrow 0} \mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s \leq 0} (\tilde{W}_s - C s) \leq \inf_{0 < s \leq 1} \tilde{W}_s - C(s - \psi_r(s))\right).$$

When $f_0(t) = 0$ for all $t > 0$, we choose $a = C\varepsilon$, and (3.2) implies that

$$\mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{-1 \leq t \leq 0} (W_t - Ct) \leq \inf_{0 < t \leq 1} (W_t - Ct)\right).$$

This shows that in this case, the upper confident limit for $\hat{f}(0)$ is of order ε (parametric rate). This also happens when $r_0 > 0$, which is the case when f_0 is flat to the right of 0. $\square$

3.1 L^q convergence of the LS-estimator

The basis for deriving the L^q ($q > 0$) convergence of the Least Squares estimator will be Equation (3.4), together with Lemma 2.2 and a uniform integrability argument. We note that (3.4) holds for all choices of $C > 0$, as long as Equations (3.1) for a and r_a have a solution. To ensure this, we choose $\delta \in (0, 1)$ small and define $a_\delta > 0$ and $C_\delta > 0$ such that

$$F_0(\delta) = a_\delta \delta \quad \text{and} \quad a_\delta \delta^{1/2} = \varepsilon C_\delta.$$

This is possible as soon as $F_0(1) > 0$; the case $F_0(1) = 0$ is in fact easier. So for any $C \leq C_\delta$, we have $r_a \leq \delta$, and since η is increasing, we get

$$\mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s \leq 0} (W_s - Cs) \leq \inf_{0 < s \leq \tau} W_s - C(s - \psi_r(s)) + C\eta(\delta)\right).$$

Note that from the derivation of Equation (3.4), it follows that we can choose $\tau \in (0, 1)$ fixed, independent of C and ε . Now we wish to make the dependence of a on C more specific. To this end, we introduce two auxiliary functions G_0 and H_0 :

$$G_0(t) = F_0(t)/t \quad \text{and} \quad H_0(a) = a\sqrt{G_0^{-1}(a)} \quad \text{for } a \leq a_\delta.$$

Since F_0 is convex and has derivative 0 in 0, we get that G_0 is strictly increasing on the set $\{t \in [0, 1] : F_0(t) > 0\}$. This means that G_0^{-1} can be defined on $[0, a_\delta]$ in a continuous, strictly increasing manner. Therefore, H_0 will be a continuous, strictly increasing function on $[0, a_\delta]$ with $H_0(0) = 0$. Clearly,

$$r_a = G_0^{-1}(a) \quad \text{and} \quad H_0(a) = C\varepsilon.$$

We extend the definition of H_0 to $[0, \infty)$ by

$$H_0(a) = H_0(a_\delta) + a - a_\delta \quad \text{for } a \geq a_\delta.$$

In this way, H_0 remains a continuous and strictly increasing function. We define for all $C > 0$ and $\varepsilon > 0$, $H_0(a) = C\varepsilon$. We can show the following proposition, using the notation $x_+ = \max(0, x)$.

Proposition 3.2 *Suppose $\psi_r(s) < s$ for some $s \in (0, 1)$ (and hence for all $s \in (0, 1)$). With the notations as above, we have for all ε small enough, that for all $C > 0$*

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) \leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq W_\tau - \frac{1}{4}\delta C\right).$$

Proof: Since H_0 is strictly increasing, we have

$$\mathbb{P}(\hat{f}(0) \geq a) = \mathbb{P}(H_0(\hat{f}(0)_+) \geq H_0(a)) = \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C).$$

So for any $C \leq C_\delta = a_\delta \delta^{1/2} \varepsilon^{-1}$, we get

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) \leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq \inf_{0 < s \leq \tau} W_s - C(s - \psi_r(s)) + C\eta(\delta)\right).$$

What can we say when $C > C_\delta$? With a defined by $H_0(a) = C\varepsilon$, we get that $a > a_\delta$ and

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) = \mathbb{P}(\hat{f}(0) \geq a),$$

so we can use Equation (3.2) to conclude that

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) &= \mathbb{P}\left(\inf_{-1 \leq t \leq 0}(\varepsilon W_t + F_0(t) - at) \leq \inf_{0 < t \leq 1}(\varepsilon W_t + F_0(t) - at)\right) \\ &\leq \mathbb{P}\left(\inf_{-1 \leq t \leq 0}(\varepsilon W_t - at) \leq \inf_{0 < t \leq \delta}(\varepsilon W_t + a_\delta t - at)\right) \\ &\leq \mathbb{P}\left(\inf_{-1 \leq t \leq 0}(W_t - (a_\delta \varepsilon^{-1} + C - C_\delta)t) \leq \inf_{0 < t \leq \delta}(W_t - (C - C_\delta)t)\right). \end{aligned}$$

Now note that $a_\delta \varepsilon^{-1} = \delta^{-1/2} C_\delta > C_\delta$, which leads us to

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) \leq \mathbb{P}\left(\inf_{-1 \leq t \leq 0}(W_t - Ct) \leq \inf_{0 < t \leq \delta}(W_t - (C - C_\delta)t)\right).$$

Now we use that $\psi_r(s) < s$, also in view of Lemma 2.2. Choose δ so small, that $\delta < \tau$ and $\tau - \psi_r(\tau) - \eta(\delta) > \delta/2$. Then for $C \leq C_\delta$ we get

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) &\leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq \inf_{0 < s \leq \tau} W_s - C(s - \psi_r(s)) + C\eta(\delta)\right) \\ &\leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq W_\tau - \frac{1}{2}\delta C\right). \end{aligned}$$

For $C > C_\delta$ we have

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) \leq \mathbb{P}\left(\inf_{t \leq 0}(W_t - Ct) \leq W_\delta - (C - C_\delta)\delta\right).$$

Since for C big enough, we have

$$\mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq W_\delta - \frac{1}{2}\delta C\right) \leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq W_\tau - \frac{1}{2}\delta C\right),$$

we conclude that for $C \geq 2C_\delta$,

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) \leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq W_\tau - \frac{1}{2}\delta C\right).$$

Note that $\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C)$ is a decreasing function of C , so for ε small enough, which means C_δ big enough, we can conclude for all $C > 0$ that

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) \leq \mathbb{P}\left(\inf_{s \leq 0}(W_s - Cs) \leq W_\tau - \frac{1}{4}\delta C\right).$$

□

The definition of $H_0(a)$ depends on the choice of $\delta > 0$, when $a > a_\delta$, but since $\hat{f}(0) \rightarrow 0$, this should not be relevant. To prove this, we show the following corollary.

Corollary 3.3 *Suppose $\psi_r(s) < s$ for some $s \in (0, 1)$. Let $\chi : [0, \infty) \rightarrow [0, \infty)$ be such that for some constants $K > 0$ and $n \geq 1$*

$$\begin{aligned} \chi(a) &\leq H_0(a) \quad \text{for } a \leq a_\delta \\ \chi(a) &\leq KH_0(a)^n \quad \text{for } a > a_\delta. \end{aligned}$$

Then there exists constants $L_1, L_2, \gamma, \varepsilon_0 > 0$ such that for all $0 < \varepsilon < \varepsilon_0$ and $C > 0$

$$\mathbb{P}(\varepsilon^{-1}\chi(\hat{f}(0)_+) \geq C) \leq L_1 e^{-L_2 C^\gamma}.$$

Proof: Note that for $\varepsilon < 1$,

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}\chi(\hat{f}(0)_+) \geq C) &= \mathbb{P}(\varepsilon^{-1}\chi(\hat{f}(0)_+) \geq C \wedge \hat{f}(0) \leq a_\delta) + \mathbb{P}(\varepsilon^{-1}\chi(\hat{f}(0)_+) \geq C \wedge \hat{f}(0) > a_\delta) \\ &\leq \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) + \mathbb{P}(K\varepsilon^{-1}H_0(\hat{f}(0)_+)^n \geq C) \\ &\leq \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) + \mathbb{P}(\varepsilon^{-1/n}H_0(\hat{f}(0)_+) \geq K^{-1/n}C^{1/n}) \\ &\leq \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq C) + \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)_+) \geq K^{-1/n}C^{1/n}) \\ &\leq L_1 e^{-L_2 C^\gamma}, \end{aligned}$$

for some choice of $L_1, L_2, \gamma, \varepsilon_0 > 0$ and all $\varepsilon < \varepsilon_0$. In the last step we used Proposition 3.2 and Equation (2.1). $\square$

To see how we can use Corollary 3.3, let us assume that $\psi_r(s) < s$ and that for positive x in some neighbourhood of 0, we have

$$f_0(x) \lesssim x^\alpha,$$

for some $\alpha > 0$. Then $F_0(x) \lesssim x^{\alpha+1}$, so $G_0(x) \lesssim x^\alpha$. Therefore, $G^{-1}(a) \gtrsim a^{1/\alpha}$, and

$$H_0(a) \geq Ra^{\frac{2\alpha+1}{2\alpha}},$$

for some $R > 0$, at least for $0 \leq a \leq a_\delta$ if we choose $\delta > 0$ small enough. Now define for all $a > 0$

$$\chi(a) = Ra^{\frac{2\alpha+1}{2\alpha}}.$$

Corollary 3.3 then shows that for all $C > 0$

$$\mathbb{P}(\varepsilon^{-1}\chi(\hat{f}(0)_+) \geq C) = \mathbb{P}\left(\varepsilon^{-\frac{2\alpha}{2\alpha+1}}\hat{f}(0) \geq (C/R)^{\frac{2\alpha}{2\alpha+1}}\right) \leq L_1 e^{-L_2 C^\gamma},$$

and this proves that for any $q > 0$,

$$\lim_{\varepsilon \rightarrow 0} \mathbb{E} \left(\left(\varepsilon^{-\frac{2\alpha}{2\alpha+1}} \hat{f}(0)_+ \right)^q \right) < +\infty.$$

Of course we can get a similar result for $\hat{f}(0)_-$ and for $|\hat{f}(0)|$. The condition $\psi_r(s) < s$ does not affect the rate of the estimator. It is only necessary to get control over the tail of the rescaled LS estimator.

3.2 Limiting distribution of the Least Squares estimator

Our methods also allow us to derive non-standard limiting distributions for the Least Squares estimator. These limiting distributions only exist when f_0 is somehow “regular” near 0. The precise conditions are described in the following theorem and will use Lemma 2.3. We start with the rate equations: for $\varepsilon > 0$ and $C > 0$ we define a, r_a, b and r_b by

$$F_0(r_a) = ar_a, \quad F_0(-r_b) = br_b \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = C\varepsilon.$$

Theorem 3.4 *Suppose that*

$$\lim_{\varepsilon \rightarrow 0} \frac{r_a}{r_b} = \gamma,$$

with $\gamma \in [0, \infty)$. Furthermore, suppose that for $s \geq 0$,

$$\lim_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} = s^\alpha$$

for $\alpha > 1$ (see also Lemma 2.3). Then, if W_s ($s \in \mathbb{R}$) denotes twosided standard Brownian motion,

$$\lim_{\varepsilon \rightarrow 0} \mathbb{P}(\hat{f}(0) > a) = \mathbb{P}\left(\inf_{s \leq 0} (W_s + C\gamma^{\alpha-1/2}|s|^\alpha - Cs) \leq \inf_{s \geq 0} (W_s + C|s|^\alpha - Cs)\right)$$

If $\lim_{\varepsilon \rightarrow 0} r_a/r_b = +\infty$, then

$$\lim_{\varepsilon \rightarrow 0} \mathbb{P}(\hat{f}(0) > 0) = 0.$$

Proof: We start with assuming that $\gamma > 0$. Since $r_a/r_b \rightarrow \gamma$ and $ar_a^{1/2} = br_b^{1/2}$, we see that $a/b \rightarrow \gamma^{-1/2}$ and $F_0(r_a)/F_0(-r_b) \rightarrow \gamma^{1/2}$ (since $F_0(r_a) = ar_a$ and $F_0(-r_b) = br_b$). For each $\eta > 0$, we have that $(\gamma - \eta)r_b \leq r_a \leq (\gamma + \eta)r_b$, for ε small enough. Therefore

$$\limsup_{\varepsilon \rightarrow 0} \frac{F_0(r_a)}{F_0(\gamma r_b)} \leq \lim_{\varepsilon \rightarrow 0} \frac{F_0((\gamma + \eta)r_b)}{F_0(\gamma r_b)} = \left(\frac{\gamma + \eta}{\gamma} \right)^\alpha.$$

We used that, since $\psi_r(s) > 0$ for $s \in (0, 1]$, we have that $r_a \rightarrow 0$ and $r_b \rightarrow 0$. The inequality holds for all $\eta > 0$, and we can show a similar inequality for the $\liminf$, which means that

$$\lim_{\varepsilon \rightarrow 0} \frac{F_0(r_a)}{F_0(\gamma r_b)} = 1.$$

Since r_a and r_b are decreasing continuous functions of ε , we have shown that in fact

$$\lim_{t \downarrow 0} \frac{F_0(\gamma t)}{F_0(-t)} = \gamma^{1/2}.$$

This in turn implies that

$$\lim_{t \downarrow 0} \frac{F_0(-st)}{F_0(-t)} = \lim_{t \downarrow 0} \frac{F_0(+\gamma st)}{F_0(+\gamma t)} = s^\alpha.$$

So the rescaled behavior of F_0 to the left of zero is equal to the behavior of F_0 to the right of zero.

The rest of the proof is based on Equation (3.3):

$$\begin{aligned} \mathbb{P}(\hat{f}(0) \geq a) &= \mathbb{P} \left(\inf_{-r_a^{-1} \leq s \leq 0} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) \leq \right. \\ &\quad \left. \inf_{0 < s \leq r_a^{-1}} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) \right). \end{aligned}$$

Here, W_s is twosided Brownian motion. Note that we can rewrite this equation as

$$\mathbb{P}(\hat{f}(0) \geq a) = \mathbb{P} \left(\operatorname{argmin}_{s \in [-r_a^{-1}, r_a^{-1}]} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) \leq 0 \right).$$

Using Lemma 2.3, we conclude that there exists a family of functions $\eta_t(s)$ on $[0, \infty)$, such that $\eta_t \rightarrow 0$ uniformly on compacta as $t \rightarrow 0$, with

$$F_0(st) = s^\alpha F_0(t) + \eta_t(s) F_0(t) \quad (t \in \mathbb{R}).$$

This shows that for $s \in [0, \infty)$, we have

$$\begin{aligned} W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs &= W_s + Cs^\alpha + C\eta_t(s) - Cs \\ &\longrightarrow W_s + Cs^\alpha - Cs, \end{aligned}$$

uniformly on compacta. For $s \in (-\infty, 0]$, we have to be a bit more careful:

$$\begin{aligned} \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) &= \varepsilon^{-1} r_a^{-1/2} \left(\frac{r_a}{r_b} \right)^\alpha |s|^\alpha F_0(-r_b) + \varepsilon^{-1} r_a^{-1/2} \eta_t(|s| r_a/r_b) F_0(-r_b) \\ &= \left(\frac{r_a}{r_b} \right)^{\alpha-1/2} |s|^\alpha \varepsilon^{-1} r_b^{1/2} b + \left(\frac{r_a}{r_b} \right)^{-1/2} \eta_t(|s| r_a/r_b) \varepsilon^{-1} r_b^{1/2} b \\ &\rightarrow C\gamma^{\alpha-1/2} |s|^\alpha, \end{aligned}$$

uniformly on compacta. We have shown that uniformly on compacta

$$W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs \rightarrow \begin{cases} W_s + Cs^\alpha - Cs & \text{for } s \geq 0, \\ W_s + C\gamma^{\alpha-1/2}|s|^\alpha - Cs & \text{for } s \leq 0, \end{cases}$$

Now we wish to use Theorem 2.7 from [KIM,POLLARD (1990)], p.198. This Theorem implies that the location of the minimum of the process $W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs$ converges in distribution to the location of the minimum of its limiting process, provided that this location is $O_p(1)$. To show this last condition, we consider for $M > 1$

$$\mathbb{P} \left(\operatorname{argmin}_{s \in [-r_a^{-1}, r_a^{-1}]} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) > M \right) \leq \mathbb{P} \left(\inf_{s \geq M} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) < 0 \right).$$

Now we use that for ε small enough, $F_0(Mr_a) \geq M^\alpha F_0(r_a) - F_0(r_a)$, so for $s \geq M$, using convexity of F_0 , we get

$$F_0(sr_a) \geq sF_0(Mr_a)/M \geq M^{\alpha-1} ar_a s - ar_a s/M.$$

Using this we get

$$\mathbb{P} \left(\inf_{s \geq M} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) < 0 \right) \leq \mathbb{P} \left(\inf_{s \geq M} (W_s + CM^{\alpha-1}s - Cs/M - Cs) < 0 \right).$$

Clearly, this last probability goes to zero exponentially fast as $M \rightarrow +\infty$, since $\alpha > 1$. Now we have to check the lower bound for the location of the minimum:

$$\begin{aligned} \mathbb{P} \left(\operatorname{argmin}_{s \in [-r_a^{-1}, r_a^{-1}]} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) < -M \right) &\leq \mathbb{P} \left(\inf_{s \leq -M} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs) < 0 \right) \\ &\leq \mathbb{P} \left(\inf_{s \leq -M} (W_s - Cs) < 0 \right). \end{aligned}$$

This last probability again goes to zero exponentially fast as $M \rightarrow +\infty$. This proves the Theorem for $\gamma > 0$. When $\gamma = 0$, so $r_a/r_b \rightarrow 0$, the above reasoning goes through, except for the convergence of the process $W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s) - Cs$ for $s \in (-\infty, 0]$. We need to show that

$$\varepsilon^{-1} r_a^{-1/2} F_0(r_a s) \rightarrow 0,$$

uniformly on compact subsets of $(-\infty, 0]$. Fix a compact set $[-M, 0]$ and choose ε so small, that $Mr_a \leq r_b$. Then for all $s \in [-M, 0]$,

$$\begin{aligned} |\varepsilon^{-1} r_a^{-1/2} F_0(r_a s)| &\leq \varepsilon^{-1} r_a^{-1/2} F_0(-r_b) |s| \frac{r_a}{r_b} \\ &\leq C \left(\frac{r_a}{r_b} \right)^{1/2} M \\ &\rightarrow 0. \end{aligned}$$

Finally we need to prove the last statement. For this, we directly use Equation (3.2):

$$\mathbb{P}(\hat{f}(0) \geq 0) = \mathbb{P} \left(\inf_{-1 \leq t \leq 0} (\varepsilon W_t + F_0(t)) \leq \inf_{0 < t \leq 1} (\varepsilon W_t + F_0(t)) \right).$$

Now we take the usual rescaling, replacing t by $r_a s$ and multiplying with $r_a^{-1/2}$:

$$\mathbb{P}(\hat{f}(0) \geq 0) = \mathbb{P}\left(\inf_{-r_a^{-1} \leq s \leq 0} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s)) \leq \inf_{0 < s \leq r_a^{-1}} (W_s + \varepsilon^{-1} r_a^{-1/2} F_0(r_a s))\right).$$

Choose ε small such that $r_a \geq r_b$. Then if $s \leq -r_b/r_a$, we have $F_0(r_a s) \geq |s|F_0(-r_b)r_a/r_b$, whereas if $-r_b/r_a \leq s \leq 0$, we still have that $F_0(r_a s) \geq 0$, so

$$\begin{aligned} \mathbb{P}(\hat{f}(0) \geq 0) &\leq \mathbb{P}\left(\inf_{-r_a^{-1} \leq s \leq -r_b/r_a} (W_s + \left(\frac{r_a}{r_b}\right)^{1/2} C|s|) \leq \inf_{0 < s \leq 1} W_s + Cs\right) \\ &\quad + \mathbb{P}\left(\inf_{-r_b/r_a \leq s \leq 0} W_s \leq \inf_{0 < s \leq 1} W_s + Cs\right). \end{aligned}$$

Since $r_a/r_b \rightarrow +\infty$, these two probabilities clearly go to zero, since $\inf_{0 \leq s \leq 1} W_s + Cs < 0$ with probability 1. Note that for this last result, we do not need any other assumptions on F_0 . $\square$

As before, we introduce the auxiliary function G_0 and H_0 , but now on a full neighborhood of 0: fix $\delta > 0$ and for $t \in (-\delta, \delta)$

$$G_0(t) = F_0(t)/t \quad \text{and} \quad H_0(t) = t\sqrt{|G_0^{-1}(t)|}.$$

As before, we have that both G_0 and H_0 are strictly increasing functions on $(-\delta, \delta)$. We also know that the rate equations (3.1) imply that

$$H_0(a) = C\varepsilon \quad \text{and} \quad H_0(-b) = -C\varepsilon.$$

Corollary 3.5 *Suppose*

$$\lim_{\varepsilon \rightarrow 0} \frac{r_a}{r_b} = \gamma,$$

with $\gamma \in [0, \infty)$. Furthermore, suppose that for $s \geq 0$,

$$\lim_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} = s^\alpha$$

for $\alpha > 1$ (see also Lemma 2.3). If W_s ($s \in \mathbb{R}$) denotes twosided standard Brownian motion, define the process

$$X(s) = \begin{cases} W_s + s^\alpha & \text{for } s \geq 0, \\ W_s + \gamma^{\alpha-1/2}|s|^\alpha & \text{for } s \leq 0, \end{cases}$$

and the process $\hat{X}(s)$ as the greatest convex minorant of X . Then

$$\varepsilon^{-1} H_0(\hat{f}(0)) \xrightarrow{d} \operatorname{sgn} \left(\frac{d\hat{X}}{ds}(0) \right) \left| \frac{d\hat{X}}{ds}(0) \right|^{\frac{2\alpha-1}{2\alpha-2}}.$$

Here, $\operatorname{sgn}(x)$ denotes the sign of $x \in \mathbb{R}$.

Proof: We start by considering $\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \geq C)$, for $C > 0$. We get

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \geq C) &= \mathbb{P}(\hat{f}(0) \geq a) \\ &\longrightarrow \mathbb{P}\left(\inf_{s \leq 0}(W_s + C\gamma^{\alpha-1/2}|s|^\alpha - Cs) \leq \inf_{s \geq 0}(W_s + C|s|^\alpha - Cs)\right), \end{aligned}$$

according to Theorem 3.4. Now replace s by $C^{2/(1-2\alpha)}s$, multiply left and right by $C^{-1/(1-2\alpha)}$ and use Brownian scaling to get

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \geq C) \longrightarrow \mathbb{P}\left(\inf_{s \leq 0}(W_s + \gamma^{\alpha-1/2}|s|^\alpha - C^{\frac{2\alpha-2}{2\alpha-1}}s) \leq \inf_{s \geq 0}(W_s + |s|^\alpha - C^{\frac{2\alpha-2}{2\alpha-1}}s)\right).$$

Using the switch relation for the greatest convex minorant, we see that

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \geq C) &\longrightarrow \mathbb{P}\left(\frac{d\hat{X}}{ds}(0) \geq C^{\frac{2\alpha-2}{2\alpha-1}}\right) \\ &= \mathbb{P}\left(\operatorname{sgn}\left(\frac{d\hat{X}}{ds}(0)\right) \left|\frac{d\hat{X}}{ds}(0)\right|^{\frac{2\alpha-1}{2\alpha-2}} \geq C\right). \end{aligned}$$

When $\gamma = 0$, the proof is finished, since in that case

$$\mathbb{P}\left(\frac{d\hat{X}}{ds}(0) \geq 0\right) = 1.$$

Now suppose $\gamma > 0$. We have seen in the proof of Theorem 3.4 that the scaling of F_0 to the left of 0 is the same as the scaling to the right, so for all $s \geq 0$

$$\lim_{t \rightarrow 0} \frac{F_0(st)}{F_0(t)} = s^\alpha.$$

Consider for $C > 0$

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \leq -C) &= \mathbb{P}(\hat{f}(0) \leq -b) \\ &\longrightarrow \mathbb{P}\left(\inf_{s \leq 0}(W_s + C\gamma^{-\alpha+1/2}|s|^\alpha - Cs) \leq \inf_{s \geq 0}(W_s + C|s|^\alpha - Cs)\right), \end{aligned}$$

using Theorem 3.4 for the left hand side of the origin (that is, interchange a and b and replace γ by $1/\gamma$). Now replace s by $-\gamma C^{2/(1-2\alpha)}s$, multiply left and right by $\gamma^{-1/2}C^{-1/(1-2\alpha)}$ and use Brownian scaling to get

$$\mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \leq -C) \longrightarrow \mathbb{P}\left(\inf_{s \geq 0}(W_s + |s|^\alpha + C^{\frac{2\alpha-2}{2\alpha-1}}s) \leq \inf_{s \leq 0}(W_s + \gamma^{\alpha-1/2}|s|^\alpha + C^{\frac{2\alpha-2}{2\alpha-1}}s)\right).$$

Note that the two infima have switched sides because of the scaling with a negative constant. Again using the switch relation we get

$$\begin{aligned} \mathbb{P}(\varepsilon^{-1}H_0(\hat{f}(0)) \leq -C) &\longrightarrow \mathbb{P}\left(\frac{d\hat{X}}{ds}(0) \leq -C^{\frac{2\alpha-2}{2\alpha-1}}\right) \\ &= \mathbb{P}\left(\operatorname{sgn}\left(\frac{d\hat{X}}{ds}(0)\right) \left|\frac{d\hat{X}}{ds}(0)\right|^{\frac{2\alpha-1}{2\alpha-2}} \leq -C\right). \end{aligned}$$

This proves the corollary. $\square$

The condition that F_0 is regularly varying around 0 with parameter $\alpha > 1$, implies that the function H_0 is regularly varying around 0 with parameter $\beta = (2\alpha - 1)/(2\alpha - 2)$, so for all $s \geq 0$

$$\lim_{t \rightarrow 0} \frac{H_0(st)}{H_0(t)} = s^\beta.$$

It is well known from the theory of regularly varying functions that this limit is uniform for $s \in [1/M, M]$, for any $M > 1$. This will help us prove the next corollary:

Corollary 3.6 *With the conditions and notations from Corollary 3.5, we can show that*

$$\frac{\hat{f}(0)_+}{H_0^{-1}(\varepsilon)} \xrightarrow{d} \frac{d\hat{X}}{ds}(0)_+ \quad \text{and} \quad \frac{\hat{f}(0)_-}{-H_0^{-1}(-\varepsilon)} \xrightarrow{d} \frac{d\hat{X}}{ds}(0)_-.$$

Proof: We wish to show that

$$\frac{H_0(\hat{f}(0))}{\varepsilon} \cdot \left| \frac{H_0^{-1}(\text{sgn}(\hat{f}(0))\varepsilon)}{\hat{f}(0)} \right|^\beta \text{sgn}(\hat{f}(0)) \rightarrow 1 \quad \text{in probability.} \quad (3.5)$$

Suppose $\eta > 0$. Using Corollary 3.5, there exists $M > 1$ such that for all ε small enough

$$\mathbb{P}\left(H_0(\hat{f}(0)) \in [-\varepsilon M, -\varepsilon/M] \cup [\varepsilon/M, \varepsilon M]\right) \geq 1 - \eta.$$

If $H_0(\hat{f}(0)) \in [\varepsilon/M, \varepsilon M]$, we know that

$$\frac{H_0^{-1}(\varepsilon/M)}{H_0^{-1}(\varepsilon)} \leq \frac{\hat{f}(0)}{H_0^{-1}(\varepsilon)} \leq \frac{H_0^{-1}(\varepsilon M)}{H_0^{-1}(\varepsilon)}.$$

Since H_0^{-1} is regularly varying around 0 with parameter $1/\beta$, we then know that for ε small enough,

$$\frac{1}{2}M^{-1/\beta} \leq \frac{\hat{f}(0)}{H_0^{-1}(\varepsilon)} \leq 2M^{1/\beta}.$$

A similar reasoning shows that if $H_0(\hat{f}(0)) \in [-\varepsilon/M, -\varepsilon M]$, then for ε small enough,

$$\frac{1}{2}M^{-1/\beta} \leq \frac{\hat{f}(0)}{H_0^{-1}(-\varepsilon)} \leq 2M^{1/\beta}.$$

Now consider

$$\varepsilon^{-1}H_0(\hat{f}(0)) = \text{sgn}(\hat{f}(0))H_0\left(H_0^{-1}(\text{sgn}(\hat{f}(0))\varepsilon) \frac{\hat{f}(0)}{H_0^{-1}(\text{sgn}(\hat{f}(0))\varepsilon)}\right)/H_0(H_0^{-1}(\text{sgn}(\hat{f}(0))\varepsilon)).$$

Since $H_0(st)/H_0(t) \rightarrow s^\beta$ uniform for s in compact subsets of $(0, \infty)$, we can conclude with probability higher than $1 - \eta$, that for ε small enough,

$$\left| \varepsilon^{-1}H_0(\hat{f}(0)) - \text{sgn}(\hat{f}(0)) \left(\frac{\hat{f}(0)}{H_0^{-1}(\text{sgn}(\hat{f}(0))\varepsilon)} \right)^\beta \right| < \eta/M \quad \text{and} \quad \left| \varepsilon^{-1}H_0(\hat{f}(0)) \right| \geq 1/M.$$

This proves (3.5). Corollary 3.5 then immediately shows that

$$\frac{\text{sgn}(\hat{f}(0))\hat{f}(0)}{H_0^{-1}(\text{sgn}(\hat{f}(0))\varepsilon)} \xrightarrow{d} \frac{d\hat{X}}{ds}(0).$$

This can be written in a nicer way when we look at $\hat{f}(0)_+$ and $\hat{f}(0)_-$:

$$\frac{\hat{f}(0)_+}{H_0^{-1}(\varepsilon)} \xrightarrow{d} \frac{d\hat{X}}{ds}(0)_+$$

and

$$\frac{\hat{f}(0)_-}{-H_0^{-1}(-\varepsilon)} \xrightarrow{d} \frac{d\hat{X}}{ds}(0)_-.$$

□

Suppose f_0 is differentiable in 0 with $f'_0(0) > 0$. Then

$$\frac{F_0(st)}{F_0(t)} = \frac{\frac{1}{2}s^2t^2f'_0(0) + o(t^2)}{\frac{1}{2}t^2f'_0(0) + o(t^2)} \rightarrow s^2 \quad (t \rightarrow 0).$$

Furthermore, $G_0(t) = F_0(t)/t = \frac{1}{2}f'_0(0)t + o(t)$, which implies that $G_0^{-1}(t) = 2f'_0(0)^{-1}t + o(t)$, so

$$H_0(t) = \sqrt{2}f'_0(0)^{-1/2}t^{3/2} + o(t^{3/2}).$$

This means that

$$H_0^{-1}(\varepsilon) = \left(\frac{1}{2}f'_0(0)\right)^{1/3} \varepsilon^{2/3} + o(\varepsilon^{2/3}).$$

Define $X(s) = W_s + s^2$, with W_s twosided Brownian motion, and define $\hat{X}$ as the greatest convex minorant of X . Then Corollary 3.6 tells us that

$$\left(\frac{1}{2}f'_0(0)\right)^{-1/3} \varepsilon^{-2/3} \hat{f}(0) \xrightarrow{d} \frac{d\hat{X}}{ds}(0),$$

in accordance with the classical result by Brunk in [BRUNK (1970)], when translated to the white noise model, except that we do not need a continuous derivative of f_0 in a neighbourhood of 0, we just need the existence of the derivative in 0.

3.3 Optimality of the rate

We wish to show that the rate for the LS-estimator is “locally optimal” in the following (non-precise) sense: for each monotone L^2 -function f_0 , there exists a sequence of alternative monotone L^2 -functions f_1 , such that the rate of the LS-estimator for f_0 and f_1 cannot both be significantly improved by any other estimator. To be more precise, we will prove the following theorem:

Theorem 3.7 Choose two significance levels $\alpha \in (0, 1)$ and $\beta \in (0, 1/2)$. There exist $\eta > 0$, such that for all $\varepsilon > 0$ small enough, we can find a monotone L^2 -function f_1 (close to f_0), and we can find a rate $\gamma(\varepsilon)$ with

$$\limsup_{\varepsilon \rightarrow 0} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{f}(0) - f_i(0)| \geq \gamma(\varepsilon) \right) \leq \alpha$$

and

$$\liminf_{\varepsilon \rightarrow 0} \inf_{\hat{\theta}} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq \eta \cdot \gamma(\varepsilon) \right) > \beta,$$

where $\hat{\theta}(Y)$ is any estimator of $f(0)$ based on the data Y .

Remark 1: One may want to choose different rate-functions γ_0 and γ_1 for the two different functions f_0 and f_1 , but it seemed natural to take them equal. In any case, this statement is stronger.

Remark 2: Choose an event $A \subset C([-1, 1])$ such that $\mathbb{P}_{f_0}(Y \in A) \geq 1/2$ and $\mathbb{P}_{f_1}(Y \notin A) \geq 1/2$. Define the estimator

$$\hat{\theta}(Y) = f_0(0)1_A(Y) + f_1(0)1_{A^c}(Y).$$

Then for any choice of η and γ , we would have

$$\max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq \eta \cdot \gamma(\varepsilon) \right) \leq \frac{1}{2},$$

which is why in Theorem 3.7, we choose $\beta \in (0, 1/2)$.

Proof of Theorem 3.7: Choose $\varepsilon > 0$ small enough such that the equations

$$F_0(r_a) = ar_a, \quad F_0(-r_b) = br_b \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = C\varepsilon$$

have solutions for some fixed $C > 0$ with

$$\frac{2}{\sqrt{2\pi}C} \leq \alpha.$$

Suppose that for this ε , $a \geq b$. The case $a < b$ can be handled analogously. Define for some fixed $0 < \delta \leq 1$

$$f_1(t) = \begin{cases} \delta a & \text{if } t \geq 0 \text{ and } f_0(t) \leq \delta a, \\ f_0(t) & \text{otherwise.} \end{cases}$$

Then f_1 is a monotone L^2 -function. Note that f_1 will be discontinuous in 0. Define

$$\gamma(\varepsilon) = 2a.$$

Then Theorem 3.1 together with Lemma 2.2 shows that (remember that $a \geq b$)

$$\mathbb{P}_{f_0} \left(|\hat{f}(0)| \geq \gamma(\varepsilon) \right) \leq \alpha.$$

Since $f_1 \geq f_0$, it easily follows that

$$\mathbb{P}_{f_1} \left(\hat{f}(0) - \delta a \leq -2a \right) \leq \mathbb{P}_{f_0} \left(\hat{f}(0) \leq -a \right) \leq \frac{1}{\sqrt{2\pi}C}.$$

Now we focus on $\mathbb{P}_{f_1}(\hat{f}(0) \geq (2 + \delta)a)$. Define

$$F_1(t) = \int_0^t f_1(s) ds.$$

We can use Equation (3.3) for the situation where the underlying function is f_1 :

$$\begin{aligned} \{\hat{f}(0) \geq 2a\} &= \left\{ \inf_{-r_a^{-1} \leq s \leq 0} (r_a^{-1/2} W_{r_a s} + \varepsilon^{-1} r_a^{-1/2} F_1(r_a s) - 2\varepsilon^{-1} r_a^{1/2} a s) \leq \right. \\ &\quad \left. \inf_{0 < s \leq r_a^{-1}} (r_a^{-1/2} W_{r_a s} + \varepsilon^{-1} r_a^{-1/2} F_1(r_a s) - 2\varepsilon^{-1} r_a^{1/2} a s) \right\}. \end{aligned}$$

Again we have that $F_1(s) \geq 0$ for $s \leq 0$. Define $s_a = \inf\{t > 0 : f_0(t) \geq a\}$. Clearly, $s_{\delta a} \leq r_a$. We easily check that for $s \geq s_{\delta a}$, $F_1(s) = \delta a s_{\delta a} + F_0(s) - F_0(s_{\delta a})$. This implies that $F_1(r_a) \leq (1 + \delta) a r_a \leq 2 a r_a$. Since F_1 is convex, we conclude that for $0 \leq s \leq 1$,

$$F_1(r_a s) \leq 2 a r_a s.$$

Now we can follow the exact same steps as in the proof of Theorem 3.1, starting at Equation (3.3), to conclude that

$$\mathbb{P}_{f_1}(\hat{f}(0) \geq 2a) \leq \frac{1}{2\sqrt{2\pi}C}.$$

This clearly shows that

$$\mathbb{P}_{f_1}(|\hat{f}(0) - f_1(0)| > \gamma(\varepsilon)) = \mathbb{P}_{f_1}(\hat{f}(0) > (2 + \delta)a) + \mathbb{P}_{f_1}(\hat{f}(0) < -(2 - \delta)a) \leq \alpha.$$

So we have shown that our rate γ satisfies the first requirement of the theorem.

Now define μ as the probability measure on $C([-1, 1])$ that corresponds to standard two-sided Brownian motion, and denote with P_0 and P_1 the measures corresponding to the model with f_0 and f_1 respectively. It is well known that

$$\frac{dP_i}{d\mu}(W) = \exp\left(\varepsilon^{-1} \int f_i(t) dW(t) - \frac{1}{2} \varepsilon^{-2} \int f_i(t)^2 dt\right).$$

Therefore

$$\frac{dP_1}{dP_0}(W) = \exp\left(\varepsilon^{-1} \int (f_1(t) - f_0(t)) dW(t) - \frac{1}{2} \varepsilon^{-2} \int f_1(t)^2 dt + \frac{1}{2} \varepsilon^{-2} \int f_0(t)^2 dt\right).$$

This means that

$$\begin{aligned} \|P_1 - P_0\|_1^2 &\leq \mathbb{E}_{P_0} \left(\frac{dP_1}{dP_0}(W) - 1 \right)^2 \\ &= \mathbb{E}_{P_0} \left(\frac{dP_1}{dP_0}(W) \right)^2 - 1 \\ &= \mathbb{E}_{\mu} \left(\exp\left(\varepsilon^{-1} \int (2f_1(t) - f_0(t)) dW(t) - \varepsilon^{-2} \int f_1(t)^2 dt + \frac{1}{2} \varepsilon^{-2} \int f_0(t)^2 dt\right) \right) - 1 \\ &= \exp\left(\frac{1}{2} \varepsilon^{-2} \int (2f_1(t) - f_0(t))^2 dt - \varepsilon^{-2} \int f_1(t)^2 dt + \frac{1}{2} \varepsilon^{-2} \int f_0(t)^2 dt\right) - 1 \\ &= \exp\left(\varepsilon^{-2} \int (f_1(t) - f_0(t))^2 dt\right) - 1. \end{aligned}$$

We immediately see that

$$\int (f_1(t) - f_0(t))^2 dt \leq \delta^2 a^2 s_{\delta a} \leq \delta^2 a^2 r_a$$

so we conclude that

$$\|P_1 - P_0\| \leq \sqrt{\exp(C^2 \delta^2) - 1}.$$

Choose $\delta \in (0, 1]$ small enough, such that $\|P_1 - P_0\| < 2 - 4\beta$. Choose $\eta = \delta/4$. Denote with p_i the density of P_i with respect to μ ($i = 0, 1$). We have that for any estimator $\hat{\theta}$

$$\begin{aligned} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq 2\eta a \right) &\geq \frac{1}{2} \sum_{i=0}^1 \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq 2\eta a \right) \\ &= \frac{1}{2} \mathbb{E}_{\mu} \left(1_{\{|\hat{\theta}(Y)| \geq 2\eta a\}} p_0(W) + 1_{\{|\hat{\theta}(Y) - \delta a| \geq 2\eta a\}} p_1(W) \right) \\ &\geq \frac{1}{2} \mathbb{E}_{\mu} (\min(p_0(W), p_1(W))) \\ &= \frac{1}{2} (1 - \frac{1}{2} \|P_1 - P_0\|) \\ &> \beta. \end{aligned}$$

This proves the theorem. □

4 The LS-estimator with measurements on a grid

In this section we wish to show that in the model

$$Y_i = f_0(x_i) + \varepsilon_i,$$

where $x_i = i/n$ ($i = -n, \dots, n$) (so our measurements are taken on a grid) and ε_i iid, we will get results analogous to the white noise model. The key observation is that when we take measurements on a grid, we can represent the least squares estimator $\hat{f}$ as the derivative of a greatest convex minorant, just as we did with the white noise model. When we define

$$\hat{g}(t) = \sum_{i=-n}^n Y_i 1_{\{x_{i-1} < t \leq x_i\}},$$

with $x_{-n-1} = -1 - 1/n$, and for $s \in [-1 - 1/n, 1]$

$$\hat{G}(s) = \int_0^s \hat{g}(t) dt,$$

we can define

$$\hat{F}(t) = \sup\{\phi(t) \mid \phi \text{ affine and } \forall -1 - \frac{1}{n} \leq s \leq 1 : \phi(s) \leq \hat{G}(s)\}.$$

Finally, the least squares estimator is defined as

$$\hat{f}(t) = \lim_{h \downarrow 0} \frac{F(t) - F(t-h)}{h}.$$

Define a and b , depending on n , as follows:

$$F_0(r_a) = ar_a, \quad F_0(-r_b) = br_b \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = Cn^{-1/2}. \quad (4.1)$$

Here, as before, $C > 0$ is some fixed constant. We have the following result:

Theorem 4.1 *With the notations as above, suppose $\text{Var}(\varepsilon_i) = \sigma^2 < +\infty$. Then*

$$\limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s \leq 0} W_s - \frac{C}{\sigma}s \leq \inf_{0 < s \leq 1} W_s - \frac{C}{\sigma}(s - \psi_r(s))\right)$$

and

$$\limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \leq -b) \leq \mathbb{P}\left(\inf_{s \leq 0} W_s - \frac{C}{\sigma}s \leq \inf_{0 < s \leq 1} W_s - \frac{C}{\sigma}(s - \psi_l(s))\right).$$

Proof: We start by bounding $\mathbb{P}(\hat{f}(0) \geq a)$; the bound for $\mathbb{P}(\hat{f}(0) \leq -b)$ follows completely analogously. As in (3.2), we note that

$$\{\hat{f}(0) \geq a\} = \left\{ \inf_{-1-1/n \leq t < 0} (\hat{G}(t) - at) \leq \inf_{0 \leq t \leq 1} (\hat{G}(t) - at) \right\}.$$

Define

$$\tilde{f}_0(t) = \sum_{i=-n}^n f_0(x_i) 1_{\{x_{i-1} < t \leq x_i\}}.$$

We now use a similar rescaling as with the white noise model, so $t = r_a s$ and multiplying left and right with $n^{1/2}r_a^{-1/2}$. Then $\hat{f}(0) \geq a$ precisely when

$$\begin{aligned} \inf_{-r_a^{-1}(1+1/n) \leq s < 0} \left(r_a^{-1/2} n^{1/2} \int_0^{r_a s} \sum_{i=0}^{-n} \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt + r_a^{-1/2} n^{1/2} \int_0^{r_a s} \tilde{f}_0(t) dt - (r_a n)^{1/2} a s \right) \leq \\ \inf_{0 \leq s \leq r_a^{-1}} \left(r_a^{-1/2} n^{1/2} \int_0^{r_a s} \sum_{i=1}^n \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt + r_a^{-1/2} n^{1/2} \int_0^{r_a s} \tilde{f}_0(t) dt - (r_a n)^{1/2} a s \right). \end{aligned} \quad (4.2)$$

Since f_0 is increasing, it is not hard to see that for $s \geq 0$

$$\int_0^{r_a s} \tilde{f}_0(t) dt \leq F_0(r_a s) + n^{-1} f_0(\lceil r_a s \rceil).$$

Here, $\lceil r_a s \rceil$ signifies the first grid-point bigger than $r_a s$. As before, we can use Lemma 2.1: for any $\tau \in (0, 1)$ there exists a positive continuous function η with $F_0(t) = 0 \Rightarrow \eta(t) = 0$, such that for $s \in [0, \tau]$

$$F_0(r_a s) \leq F_0(r_a) \psi_r(s) + F_0(r_a) \eta(r_a).$$

Here, $\eta(r_a) \rightarrow 0$. This means that for $0 \leq s \leq \tau$

$$r_a^{-1/2} n^{1/2} \int_0^{r_a s} \tilde{f}_0(t) dt \leq C \psi_r(s) + C \eta(r_a) + r_a^{-1/2} n^{-1/2} f_0(\lceil r_a s \rceil).$$

Furthermore, when $t \leq 0$, $\tilde{f}_0(t) \leq 0$. This means that (4.2) implies

$$\inf_{s < 0} \left(r_a^{-1/2} n^{1/2} \int_0^{r_a s} \sum_{i=0}^{-n} \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt - Cs \right) \leq \inf_{0 \leq s \leq \tau} \left(r_a^{-1/2} n^{1/2} \int_0^{r_a s} \sum_{i=1}^n \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt + C(s - \psi_r(s)) + C\eta(r_a) + \frac{a}{C} f_0(\lceil r_a s \rceil) \right).$$

Note that the process

$$s \mapsto r_a^{-1/2} n^{1/2} \int_0^{r_a s} \sum_{i=-n}^n \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt$$

converges to σW_s , in the topology of uniform convergence on compacta, where W_s is twosided standard Brownian motion; this is because $nr_a = C^2 a^{-2} \rightarrow +\infty$. Also, $a \rightarrow 0$ and $\eta(r_a) \rightarrow 0$ as $n \rightarrow \infty$, so we conclude that

$$\limsup_{n \rightarrow \infty} \mathbb{P} \left(\hat{f}(0) \geq a \right) \leq \mathbb{P} \left(\inf_{s < 0} \left(W_s - \frac{Cs}{\sigma} \right) \leq \inf_{0 \leq s \leq \tau} W_s + C(s - \psi_r(s)) \right).$$

Since this holds for any $\tau \in (0, 1)$, we have proved the theorem. $\square$

4.1 Optimality of the rate

We wish to prove an analog of Theorem 3.7 for the model with observations on a grid. We need an extra condition on the distribution of ε_i . This makes sense, because suppose that $\varepsilon_i \in \mathbb{Z}$ with probability 1, then it would be very easy to distinguish f_0 and f_1 if $f_1(0) - f_0(0) \notin \mathbb{Z}$. The condition we need is the following:

(C1) The distribution of ε_i , with $\text{Var}(\varepsilon_i) = \sigma^2 < +\infty$, has a density ϕ with respect to the Lebesgue measure, such that there exists $M > 0$ with

$$\forall a \in \mathbb{R} : \int_{-\infty}^{\infty} \left(\phi^{1/2}(y - a) - \phi^{1/2}(y) \right)^2 dy \leq Ma^2.$$

This condition would follow from Hellinger differentiability at 0 of the model $a \mapsto \phi(\cdot - a)$.

Theorem 4.2 *Suppose Condition (C1) holds. Choose two significance levels $\alpha \in (0, 1)$ and $\beta \in (0, 1/2)$. There exist $\eta > 0$, such that for all n large enough, we can find a monotone increasing function f_1 (close to f_0), and we can find a rate γ_n with*

$$\limsup_{n \rightarrow \infty} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{f}(0) - f_i(0)| \geq \gamma_n \right) \leq \alpha$$

and

$$\liminf_{n \rightarrow \infty} \inf_{\hat{\theta}} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq \eta \cdot \gamma_n \right) > \beta,$$

where $\hat{\theta}(Y)$ is any estimator of $f(0)$ based on the data Y .

Proof: We just follow the steps as in the proof of Theorem 3.7, so we define a, r_a, b and r_b as in (4.1) with $C > 0$ such that

$$\frac{2\sigma}{\sqrt{2\pi}C} \leq \alpha.$$

For fixed n , suppose that $a \geq b$. Then we define

$$\gamma_n = 2a$$

and for some fixed $0 < \delta \leq 1$

$$f_1(t) = \begin{cases} \delta a & \text{if } t \geq 0 \text{ and } f_0(t) \leq \delta a, \\ f_0(t) & \text{otherwise.} \end{cases}$$

Theorem 4.1 shows that (remembering that $a \geq b$)

$$\mathbb{P}_{f_0}(|\hat{f}(0) - f_0(0)| \geq \gamma_n) \leq \alpha.$$

Since $f_1 \geq f_0$, we again have that

$$\mathbb{P}_{f_1}(\hat{f}(0) - \delta a \leq -2a) \leq \mathbb{P}_{f_0}(\hat{f}(0) \leq -a) \leq \frac{1}{\sqrt{2\pi}C}.$$

To bound $\mathbb{P}_{f_1}(\hat{f}(0) \geq (2 + \delta)a)$, we follow the proof of Theorem 4.1, but with f_0 replaced with f_1 . Define

$$\tilde{f}_1(t) = \sum_{i=-n}^n f_1(x_i) 1_{\{x_{i-1} < t \leq x_i\}}$$

and

$$F_1(t) = \int_0^t f_1(s) ds.$$

Then, in the model using f_1 , $\hat{f}(0) > 2a$ precisely when

$$\inf_{-r_a^{-1}(1+1/n) \leq s < 0} \left(r_a^{-1/2} n^{1/2} \int_0^{ras} \sum_{i=0}^{-n} \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt + r_a^{-1/2} n^{1/2} \int_0^{ras} \tilde{f}_1(t) dt - (r_a n)^{1/2} 2as \right) \leq \\ \inf_{0 \leq s \leq r_a^{-1}} \left(r_a^{-1/2} n^{1/2} \int_0^{ras} \sum_{i=1}^n \varepsilon_i 1_{\{x_{i-1} < t \leq x_i\}} dt + r_a^{-1/2} n^{1/2} \int_0^{ras} \tilde{f}_1(t) dt - (r_a n)^{1/2} 2as \right).$$

Now, following the steps after Equation (4.2), and using the fact that, as in the proof of Theorem 3.7, for $0 \leq s \leq 1$,

$$F_1(r_a s) \leq 2as,$$

we conclude that γ_n satisfies the first requirement of the theorem.

Now we have to note that in the model with measurements on a grid, the data $Y \in \mathbb{R}^{2n+1}$. As a dominating measure μ we just take the Lebesgue measure, and we get that the density p_i of the data Y , when we are in the model

$$Y_j = f_i(x_j) + \varepsilon_j,$$

is given by

$$p_i(y) = \prod_{j=-n}^n \phi(y_j - f_i(x_j)).$$

Define

$$\begin{aligned} \Delta_j &= \int_{-\infty}^{\infty} \left(\phi^{1/2}(y - f_1(x_j)) - \phi^{1/2}(y - f_0(x_j)) \right)^2 dy \\ &= \int_{-\infty}^{\infty} \left(\phi^{1/2}(y - (f_1(x_j) - f_0(x_j))) - \phi^{1/2}(y) \right)^2 dy. \end{aligned}$$

Let $H^2(p_0, p_1)$ denote the squared Hellinger distance between p_0 and p_1 . Then it is a standard property of the Hellinger distance that

$$H^2(p_0, p_1) \leq \sum_{j=-n}^n \Delta_j \quad (4.3)$$

But note that when we define $s_a = \inf\{t > 0 : f_0(t) \geq a\} \leq r_a$, we get that $\Delta_j = 0$ whenever $j < 0$ or $j > ns_{\delta a}$. Furthermore, using Condition **(C1)**, we have that

$$\Delta_j \leq M\delta^2 a^2. \quad (4.4)$$

This shows that

$$\begin{aligned} \|P_1 - P_0\|_1 &\leq 2\sqrt{H^2(p_0, p_1)} \\ &\leq 2\sqrt{(ns_{\delta a} + 1)M\delta^2 a^2} \\ &\leq 2\sqrt{4nr_a a^2 \delta^2 M} \\ &= 4C\delta\sqrt{M}. \end{aligned} \quad (4.5)$$

It follows that we can choose $\delta > 0$ small enough such that $\|P_1 - P_0\|_1 < 2 - 4\beta$. The rest of the proof now follows the proof of Theorem 3.7. $\square$

5 The LS-estimator with measurements on random points

In this section we consider the model

$$Y_i = f_0(X_i) + \varepsilon_i,$$

where $X_1, \dots, X_n$ is an iid sample in $[-1, 1]$ with distribution function G , independent of the ε_i 's. We again wish to estimate $f_0(0)$, but our LS-estimator is slightly more complicated now. The idea is to identify the order statistic $X_{(i)}$ with i , and calculate the least squares estimator as if the measurements were done on the grid $1, \dots, n$. So we define for $0 \leq t \leq n$:

$$h(t) = \sum_{i=1}^n Y_i 1_{\{i-1 < t \leq i\}}$$

and

$$H(t) = \int_0^t h(s) ds.$$

Furthermore, we define

$$\tilde{F}(t) = \sup\{\phi(t) \mid \phi \text{ affine and } \forall 0 \leq s \leq n : \phi(s) \leq H(s)\}$$

and

$$\tilde{f}(t) = \lim_{h \downarrow 0} \frac{\tilde{F}(t) - \tilde{F}(t-h)}{h}.$$

Finally, our estimator of f_0 is defined by

$$\hat{f}(t) = \tilde{f}(m) \quad \text{with } X_{(m-1)} < t \leq X_{(m)}.$$

Here, $X_{(m)}$ is the m^{th} order statistic of $X_1, \dots, X_n$. In order to control the rate of this estimator, we need some control on how the measurement points behave around 0. We assume the following condition:

(C2) The distribution G of X_i has a density g with respect to the Lebesgue measure in a neighborhood of 0, such that g is continuous in 0 and $g(0) > 0$.

As before, our rate is defined by

$$F_0(r_a) = ar_a, \quad F_0(-r_b) = br_b \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = Cn^{-1/2},$$

where $C > 0$ is some fixed constant.

Theorem 5.1 *With the notations as above, suppose $\text{Var}(\varepsilon_i) = \sigma^2 < +\infty$ and suppose that (C2) holds. Then*

$$\limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s < 0} W_s - \frac{Cg(0)^{1/2}s}{\sigma} \leq \inf_{0 \leq s \leq 1} W_s - \frac{Cg(0)^{1/2}}{\sigma}(s - \psi_r(s))\right)$$

and

$$\limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \leq -b) \leq \mathbb{P}\left(\inf_{s < 0} W_s - \frac{Cg(0)^{1/2}s}{\sigma} \leq \inf_{0 \leq s \leq 1} W_s - \frac{Cg(0)^{1/2}}{\sigma}(s - \psi_l(s))\right).$$

Proof: We start by bounding $\mathbb{P}(\hat{f}(0) \geq a)$; the bound for $\mathbb{P}(\hat{f}(0) \leq -b)$ follows completely analogously. Define m such that $X_{(m-1)} < 0 \leq X_{(m)}$; with probability tending to 1 we can assume that $1 < m < n$ (this follows from Condition (C2)). Note that

$$\begin{aligned} \{\hat{f}(0) \geq a\} &= \{\tilde{f}(m) \geq a\} \\ &= \left\{ \inf_{0 \leq t \leq m-1} (H(t) - at) \leq \inf_{m \leq t \leq n} (H(t) - at) \right\} \\ &= \left\{ \inf_{0 \leq t \leq m-1} (H(t) - H(m-1) - a(t-m)) \leq \inf_{m \leq t \leq n} (H(t) - H(m-1) - a(t-m)) \right\}. \end{aligned}$$

We again use a similar rescaling to the one we used for the grid model, namely $t = m + nr_a s$ and multiplying left and right with $n^{-1/2} r_a^{-1/2}$. Then $\hat{f}(0) > a$ precisely when

$$\begin{aligned} & \inf_{-m(r_a n)^{-1} \leq s \leq -(r_a n)^{-1}} \left(r_a^{-1/2} n^{-1/2} \int_{m-1}^{m+nr_a s} \sum_{i=1}^{m-1} \varepsilon_i 1_{\{i-1 < t \leq i\}} dt + \right. \\ & \quad \left. r_a^{-1/2} n^{-1/2} \int_{m-1}^{m+nr_a s} \sum_{i=1}^{m-1} f_0(X_{(i)}) 1_{\{i-1 < t \leq i\}} dt - (r_a n)^{1/2} a s \right) \leq \\ & \inf_{0 \leq s \leq (n-m)(r_a n)^{-1}} \left(r_a^{-1/2} n^{-1/2} \int_{m-1}^{m+nr_a s} \sum_{i=m}^n \varepsilon_i 1_{\{i-1 < t \leq i\}} dt + \right. \\ & \quad \left. r_a^{-1/2} n^{-1/2} \int_{m-1}^{m+nr_a s} \sum_{i=m}^n f_0(X_{(i)}) 1_{\{i-1 < t \leq i\}} dt - (r_a n)^{1/2} a s \right). \end{aligned} \quad (5.1)$$

As before, we have that

$$s \mapsto r_a^{-1/2} n^{-1/2} \int_{m-1}^{m+nr_a s} \sum_{i=1}^n \varepsilon_i 1_{\{i-1 < t \leq i\}} dt$$

converges to σW_s , with W_s two-sided standard Brownian motion. Also, for $i \leq m-1$, $f_0(X_{(i)}) \leq 0$. Finally, suppose that $r_a \geq \eta > 0$ for all $n \geq 1$. Then $f_0 = 0$ on $[0, \eta]$, and it becomes very easy to bound the right-hand side of (5.1) if we limit s to this interval, which would get us the desired result (in this case we would have a parametric rate). Now assume that $r_a \rightarrow 0$; then we need that

$$(n-m)(r_a n)^{-1} \rightarrow +\infty.$$

This is true with probability 1, since with probability 1

$$m/n \rightarrow \mathbb{P}(X_1 \leq 0) < 1.$$

Furthermore, and most importantly, we need to bound for $0 \leq s \leq g(0)$

$$\int_{m-1}^{m+nr_a s} \sum_{i=m}^n f_0(X_{(i)}) 1_{\{i-1 < t \leq i\}} dt \leq \sum_{i=m}^{m+\lceil nr_a s \rceil} f_0(X_{(i)}).$$

Define $k = \lceil nr_a s \rceil + 1$ and $D = X_{(m+k)}$. When we condition on D , we know that $X_{(m)}, \dots, X_{(m+k-1)}$ is an iid sample from G restricted to $[0, D]$. This implies, using Chebyshev,

$$\mathbb{P} \left(\left| \frac{1}{k^{1/2}} \sum_{i=m}^{m+k-1} f_0(X_{(i)}) - \frac{k^{1/2}}{G([0, D])} \int_0^D f_0(t) dG(t) \right| > \lambda \mid D \right) \leq \frac{\int_0^D f_0(t)^2 dG(t)}{G([0, D]) \lambda^2} \leq f_0(D)^2 \lambda^{-2}.$$

It is not hard to see that $D \rightarrow 0$ almost surely when $n \rightarrow +\infty$, uniformly for $s \in [0, g(0)]$, which proves that

$$r_a^{-1/2} n^{-1/2} \sum_{i=m}^{m+\lceil nr_a s \rceil} f_0(X_{(i)}) = \frac{r_a^{1/2} n^{1/2} s}{G([0, D])} \int_0^D f_0(t) dG(t) + o_p(1). \quad (5.2)$$

Now D is the position of the $k + 1$ -th sample point after 0, and since $k \rightarrow \infty$ and $k/n \rightarrow 0$, it is not hard to see, keeping in mind Condition (C2), that

$$D = \frac{r_a s}{g(0)} + O_p(r_a^{1/2} n^{-1/2}).$$

Therefore,

$$G([0, D]) = r_a s(1 + o_p(1))$$

and

$$\frac{r_a^{1/2} n^{1/2} s}{G([0, D])} \left| \int_{\frac{r_a s}{g(0)}}^{\frac{r_a s}{g(0)} + O_p(r_a^{1/2} n^{-1/2})} f_0(t) dG(t) \right| \leq f_0\left(\frac{2r_a s}{g(0)}\right) g(0)(1 + o_p(1)) = o_p(1).$$

So (5.2) becomes

$$r_a^{-1/2} n^{-1/2} \sum_{i=m}^{m + \lceil nr_a s \rceil} f_0(X_{(i)}) = r_a^{-1/2} n^{1/2} g(0) F_0\left(\frac{r_a s}{g(0)}\right) (1 + o_p(1)) + o_p(1).$$

Now we use Lemma 2.1: for any $\tau \in (0, 1)$, there exists a continuous increasing function η on $[0, 1]$ with $F_0(t) = 0 \implies \eta(t) = 0$, such that for $0 \leq s \leq \tau g(0)$

$$F_0\left(\frac{r_a s}{g(0)}\right) \leq \psi_r(s/g(0)) F_0(r_a) + \eta(r_a) F_0(r_a).$$

So finally we conclude that

$$\begin{aligned} \limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \geq a) &\leq \mathbb{P}\left(\inf_{s < 0} (\sigma W_s - Cs) \leq \inf_{0 \leq s \leq \tau g(0)} \sigma W_s - C(s - g(0)\psi_r(s/g(0)))\right) \\ &= \mathbb{P}\left(\inf_{s < 0} W_s - \frac{Cg(0)^{1/2}s}{\sigma} \leq \inf_{0 \leq s \leq \tau} W_s - \frac{Cg(0)^{1/2}}{\sigma} (s - \psi_r(s))\right). \end{aligned}$$

Since this holds for any $\tau \in (0, 1)$, the theorem follows. $\square$

5.1 Optimality of the rate

We have an analogue to Theorem 4.2 for this setting as well:

Theorem 5.2 *Suppose Conditions (C1) and (C2) hold. Choose two significance levels $\alpha \in (0, 1)$ and $\beta \in (0, 1/2)$. There exist $\eta > 0$, such that for all n large enough, we can find a monotone increasing function f_1 (close to f_0), and we can find a rate γ_n with*

$$\limsup_{n \rightarrow \infty} \max_{i=0,1} \mathbb{P}_{f_i}(|\hat{f}(0) - f_i(0)| \geq \gamma_n) \leq \alpha$$

and

$$\liminf_{n \rightarrow \infty} \inf_{\hat{\theta}} \max_{i=0,1} \mathbb{P}_{f_i}(|\hat{\theta}(Y, X) - f_i(0)| \geq \eta \cdot \gamma_n) > \beta,$$

where $\hat{\theta}(Y, X)$ is any estimator of $f(0)$ based on the data (Y, X) .

Proof: We can follow the proof of Theorem 4.2 (and of Theorem 3.7), choosing the same alternative function f_1 , also using the steps in the proof of Theorem 5.1 for the alternative f_1 , right up to the point where we need to bound $\|P_1 - P_0\|$. In the random design case, our data consists of Y and X , but when we condition on X , we can use the inequalities (4.3) and (4.4), just by replacing x_j by X_j . The only difference is that the number N of X_j 's in the interval $[0, s_{\delta a}]$ is random. However, we have excellent control on N , and by looking at Equation (4.5), we can see that the relevant bound is given by

$$\mathbb{E}(\sqrt{N}) \leq \sqrt{4r_a n g(0)} \quad \text{for all } n \text{ big enough.}$$

Our conclusion is again that we can choose $\delta > 0$ such that $\|P_1 - P_0\|_1 < 2 - 4\beta$, after which we can follow the proof of Theorem 3.7. $\square$

6 The Grenander estimator for monotone densities

In this final section we wish to show that our methods also work for the Grenander estimator of a monotone density. Consider a sample $X_1, \dots, X_n$ from a monotone decreasing density f_0 on $[-1, \infty)$. Assume that f_0 is continuous in 0; we wish to estimate $f_0(0)$. Let $\mathbb{F}_n$ denote the empirical distribution function of the sample $X_1, \dots, X_n$. Define

$$\hat{F}(t) = \inf\{\phi(t) \mid \phi \text{ affine and } \forall s \geq -1 : \phi(s) \geq \mathbb{F}_n(s)\},$$

so $\hat{F}$ is the smallest concave majorant of $\mathbb{F}_n$. The Grenander estimator is now defined as

$$\hat{f}(t) = \lim_{h \downarrow 0} \frac{\hat{F}(t+h) - \hat{F}(t)}{h}.$$

To find the rate of the Grenander estimator, we define

$$F_0(t) = \int_0^t (f_0(0) - f_0(s)) ds. \tag{6.1}$$

This is a convex function such that $F'_0(0) = 0$. Since f_0 is decreasing, instead of increasing, when considering the event $\{\hat{f}(0) \geq f_0(0) + a\}$, we have to look to the *left*, instead of the right. This results in reversed rate-equations: define $a, b > 0$ such that

$$F_0(r_b) = br_b, \quad F_0(-r_a) = ar_a \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = Cn^{-1/2},$$

for some fixed $C > 0$. Again we define

$$\psi_r(s) = \limsup_{t \downarrow 0} \frac{F_0(st)}{F_0(t)} \quad \text{and} \quad \psi_l(s) = \limsup_{t \uparrow 0} \frac{F_0(st)}{F_0(t)}.$$

We have the following theorem:

Theorem 6.1 *With the notations as above, we have that if $r_a \rightarrow 0$ and $r_b \rightarrow 0$,*

$$\limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \geq a) \leq \mathbb{P}\left(\inf_{s < 0} W_s - \frac{C}{\sqrt{f_0(0)}} s \leq \inf_{0 \leq s \leq 1} W_s - \frac{C}{\sqrt{f_0(0)}} (s - \psi_l(s))\right)$$

and

$$\limsup_{n \rightarrow \infty} \mathbb{P}(\hat{f}(0) \leq -b) \leq \mathbb{P}\left(\inf_{s < 0} W_s - \frac{C}{\sqrt{f_0(0)}} s \leq \inf_{0 \leq s \leq 1} W_s - \frac{C}{\sqrt{f_0(0)}} (s - \psi_r(s))\right).$$

Proof: As before, we will only show how to bound $\mathbb{P}(\hat{f}(0) - f(0) \geq a)$ (in fact, this corresponds to the inequality for b in the other proofs). Define

$$F(t) = \int_0^t f_0(s) ds$$

and introduce the notation $\mathbb{F}_n(0, t] = \mathbb{F}_n(t) - \mathbb{F}_n(0)$, and likewise $F(0, t]$ (which is in fact equal to $F(t)$). Note that

$$\begin{aligned} \{\hat{f}(0) \geq f_0(0) + a\} &= \left\{ \inf_{-1 \leq t \leq 0} (f_0(0)t + at - \mathbb{F}_n(t)) \geq \inf_{t \geq 0} (f_0(0)t + at - \mathbb{F}_n(t)) \right\} \\ &= \left\{ \inf_{-1 \leq t \leq 0} (f_0(0)t + at - \mathbb{F}_n(0, t]) \geq \inf_{t \geq 0} (f_0(0)t + at - \mathbb{F}_n(0, t]) \right\} \\ &= \left\{ \inf_{-1 \leq t \leq 0} (F_0(t) + at + F(0, t] - \mathbb{F}_n(0, t]) \geq \inf_{t \geq 0} (F_0(t) + at + F(0, t] - \mathbb{F}_n(0, t]) \right\} \end{aligned}$$

We choose the scaling $t = r_a s$ and multiply left and right with $n^{1/2} r_a^{-1/2}$ to get that $\hat{f}(0) \geq f_0(0) + a$ precisely when

$$\begin{aligned} \inf_{-r_a^{-1} \leq s \leq 0} \left(n^{1/2} r_a^{-1/2} F_0(r_a s) + Cs - n^{1/2} r_a^{-1/2} (\mathbb{F}_n(0, r_a s] - F(0, r_a s]) \right) \geq \\ \inf_{s \geq 0} \left(n^{1/2} r_a^{-1/2} F_0(r_a s) + Cs - n^{1/2} r_a^{-1/2} (\mathbb{F}_n(0, r_a s] - F(0, r_a s]) \right). \end{aligned} \quad (6.2)$$

Again we use Lemma 2.1, but now for the function ψ_l : for any $\tau \in (0, 1)$, there exists a continuous increasing function η on $[0, 1]$ with $F_0(t) = 0 \implies \eta(t) = 0$, such that for $-\tau \leq s \leq 0$

$$F_0(r_a s) \leq \psi_l(-s) F_0(-r_a) + \eta(r_a) F_0(-r_a).$$

We conclude that $\hat{f}(0) \geq f_0(0) + a$ implies

$$\begin{aligned} \inf_{-\tau \leq s \leq 0} \left(-n^{1/2} r_a^{-1/2} (\mathbb{F}_n(0, r_a s] - F(0, r_a s]) + C(s + \psi_l(-s)) \right) + C\eta(r_a) \geq \\ \inf_{s \geq 0} \left(Cs - n^{1/2} r_a^{-1/2} (\mathbb{F}_n(0, r_a s] - F(0, r_a s]) \right). \end{aligned}$$

What remains is to show that if $r_a \rightarrow 0$, the process

$$Y_n : s \mapsto n^{1/2} r_a^{-1/2} (\mathbb{F}_n(0, r_a s] - F(0, r_a s]) = n^{-1/2} r_a^{-1/2} \sum_{i=1}^n (1_{\{X_i \in (0, r_a s]\}} - F(0, r_a s])$$

converges in distribution, in the topology of uniform convergence on compacta, to $f_0(0)^{1/2} W_s$, where W_s is two-sided standard Brownian motion. It seems that the classical approach to this problem is the easiest one: the fact that the finite dimensional marginal distributions converge is a relatively straightforward application of the Central Limit Theorem for triangular arrays, since

we have written the process as a rescaled sum of independent zero-mean variables; it uses the fact that $F'(0) = f_0(0)$. For tightness of the sequence Y_n it suffices to show that for all $s_1 \leq s \leq s_2$ in a compact set, there exists a constant $M > 0$ such that

$$\mathbb{E} \left((Y_n(s) - Y_n(s_1))^2 (Y_n(s_2) - Y_n(s))^2 \right) \leq M(s_2 - s_1)^2. \quad (6.3)$$

It is not hard to see that the only relevant terms after taking the expectation are

$$n^{-2} r_a^{-2} \mathbb{E} \left(\left(1_{\{X_i \in (r_a s_1, r_a s]\}} - F(r_a s_1, r_a s) \right)^2 \left(1_{\{X_j \in (r_a s, r_a s_2]\}} - F(r_a s, r_a s_2) \right)^2 \right) \quad \text{with } i \neq j,$$

of which there are of the order n^2 . Since f_0 is bounded in a neighborhood of 0, we can find a constant $\tilde{M} > 0$ such that for n big enough,

$$F(r_a s_1, r_a s_2] \leq \tilde{M} r_a (s_2 - s_1).$$

This leads to (6.3). We can finally conclude that

$$\begin{aligned} \limsup_{n \rightarrow \infty} \mathbb{P} \left(\hat{f}(0) \geq f_0(0) + a \right) &\leq \mathbb{P} \left(\inf_{-\tau \leq s \leq 0} \left(f_0(0)^{1/2} W_s + C(s + \psi_l(-s)) \right) \geq \inf_{s \geq 0} (Cs + f_0(0)^{1/2} W_s) \right) \\ &= \mathbb{P} \left(\inf_{s \leq 0} \left(W_s - \frac{C}{\sqrt{f_0(0)}} s \right) \leq \inf_{0 \leq s \leq \tau} \left(W_s - \frac{C}{\sqrt{f_0(0)}} (s - \psi_l(s)) \right) \right). \end{aligned}$$

Since this holds for any $\tau \in (0, 1)$, we have proved the theorem. $\square$

When $r_a \rightarrow r_0 > 0$, the process $Y_n(s)$ does not converge to Brownian motion, but to a rescaled Brownian bridge, depending on F_0 . However, we would still have that when $C \rightarrow \infty$,

$$\mathbb{P}(\hat{f}(0) - f_0(0) > a) \rightarrow 0,$$

so a is still the correct rate (in this case the parametric rate).

6.1 Optimality of the rate

In the monotone decreasing density case we also wish to show that the Grenander estimator has the by now familiar optimality property.

Theorem 6.2 *Choose two significance levels $\alpha \in (0, 1)$ and $\beta \in (0, 1/2)$. There exist $\eta > 0$, such that for all n large enough, we can find a monotone decreasing density f_1 on $[-1, \infty)$ (close to f_0), and we can find a rate γ_n with*

$$\limsup_{n \rightarrow \infty} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{f}(0) - f_i(0)| \geq \gamma_n \right) \leq \alpha$$

and

$$\liminf_{n \rightarrow \infty} \inf_{\hat{\theta}} \max_{i=0,1} \mathbb{P}_{f_i} \left(|\hat{\theta}(Y) - f_i(0)| \geq \eta \cdot \gamma_n \right) > \beta,$$

where $\hat{\theta}(Y)$ is any estimator of $f(0)$ based on the data Y .

Proof: The proof is very similar to the previous ones, but we need to be more careful when choosing the alternative. Choose n large enough such that the equations

$$F_0(r_b) = br_b, \quad F_0(-r_a) = ar_a \quad \text{and} \quad r_a^{1/2}a = r_b^{1/2}b = Cn^{-1/2},$$

have solutions for some fixed $C > 0$ with

$$\frac{2\sqrt{f_0(0)}}{\sqrt{2\pi}C} \leq \alpha.$$

Here, F_0 is defined in (6.1). Suppose that for this n , $a \geq b$. The case $a < b$ can be handled analogously. Define for some fixed $0 < \delta \leq 1$

$$f_1(t) = \begin{cases} f_0(0) + \delta a & \text{if } t \leq 0 \text{ and } f_0(t) \leq f_0(0) + \delta a + \eta_a, \\ f_0(t) - \eta_a & \text{if } t \leq 0 \text{ and } f_0(t) > f_0(0) + \delta a + \eta_a, \\ f_0(t) & \text{if } t > 0. \end{cases}$$

Then f_1 is a monotone decreasing density, if we choose η_a such that $\int_{-1}^{\infty} f_1(t) dt = 1$. This is always possible for n big enough, unless $r_a \rightarrow r_0 > 0$ (i.e., unless f_0 is constant on $[-r_0, 0]$). However, in this case $\hat{f}(0)$ estimates $f_0(0)$ with a parametric rate (since we consider $a \geq b$), so the conclusions of the theorem will follow. From now on we will assume that $r_a \rightarrow 0$. If $b > a$, we only define $f_1(t) = f_0(t) + \eta_b$ for $t \leq 1$ and $f_0(t) \leq f_0(0) - \delta a - \eta_a$; for $t \geq 1$ we would define $f_1(t) = f_0(t)$. Define

$$s_{\delta a} = \inf\{t > 0 : f_0(-t) \geq f_0(0) + \delta a\}.$$

We have seen before that $s_{\delta a} \leq r_{\delta a} \leq r_a$. Also,

$$\int_{-s_{\delta a}}^0 (f_1(t) - f_0(t)) dt \leq \delta a s_{\delta a}.$$

This gives us an upper bound for η_a : if n is big enough, such that $f_0(-1/2) > f_0(0) + \delta a + \eta_a$, then

$$\delta a s_{\delta a} \geq \int_{-1}^{-s_{\delta a}} (f_0(t) - f_1(t)) dt \geq \int_{-1}^{-1/2} (f_0(t) - f_1(t)) dt = \frac{1}{2}\eta_a,$$

so we conclude that for n big enough

$$\eta_a \leq 2\delta a r_a.$$

Now define

$$\gamma_n = 2a.$$

Then Theorem 6.1 shows that (remember that $a \geq b$)

$$\mathbb{P}_{f_0} \left(|\hat{f}(0) - f_0(0)| \geq \gamma_n \right) \leq \alpha.$$

From the way we defined f_1 , it is clear that we can define $X^{(1)} \sim f_1$ and couple it to $X \sim f_0$, such that $X^{(1)} = X$ if $X \geq 0$, and $X \leq X^{(1)} \leq 0$ otherwise. So if we consider the empirical distribution

functions of two samples of X and $X^{(1)}$, call them $\mathbb{F}_n$ and $\mathbb{F}_n^{(1)}$, then $\mathbb{F}_n^{(1)}(t) = \mathbb{F}_n(t)$ if $t \geq 0$, and $\mathbb{F}_n^{(1)}(t) \leq \mathbb{F}_n(t)$ if $t \in [-1, 0]$. Now note that

$$\begin{aligned} \{\hat{f}^{(1)}(0) \leq f_1(0) - 2a\} &= \left\{ \inf_{-1 \leq t \leq 0} \left(f_1(0)t - 2at - \mathbb{F}_n^{(1)}(t) \right) \leq \inf_{t \geq 0} \left(f_1(0)t - 2at - \mathbb{F}_n^{(1)}(t) \right) \right\} \\ &\subset \left\{ \inf_{-1 \leq t \leq 0} \left(f_1(0)t - 2at - \mathbb{F}_n(t) \right) \leq \inf_{t \geq 0} \left(f_1(0)t - 2at - \mathbb{F}_n(t) \right) \right\} \\ &= \{\hat{f}(0) - f_0(0) \leq \delta a - 2a\}. \end{aligned}$$

So we get, using that $\delta \leq 1$,

$$\mathbb{P}_{f_1} \left(\hat{f}(0) - f_1(0) \leq -2a \right) \leq \mathbb{P}_{f_0} \left(\hat{f}(0) \leq -a \right) \leq \frac{\sqrt{f_0(0)}}{\sqrt{2\pi} C}.$$

Now we focus on $\mathbb{P}_{f_1} \left(\hat{f}(0) \geq (2 + \delta)a \right)$. Define

$$F_1(t) = \int_0^t (f_1(0) - f_1(s)) \, ds$$

and, with a slight abuse of notation,

$$F^{(1)}(t) = \int_0^t f_1(s) \, ds.$$

We can use Equation (6.2) for the situation where the underlying function is f_1 , using the coupled sample $X_1^{(1)}, \dots, X_n^{(1)}$: $\hat{f}(0) \geq f_1(0) + 2a$ precisely when

$$\begin{aligned} \inf_{-r_a^{-1} \leq s \leq 0} \left(n^{1/2} r_a^{-1/2} F_1(r_a s) + 2Cs - n^{1/2} r_a^{-1/2} (\mathbb{F}_n^{(1)}(0, r_a s] - F^{(1)}(0, r_a s]) \right) \geq \\ \inf_{s \geq 0} \left(n^{1/2} r_a^{-1/2} F_1(r_a s) + 2Cs - n^{1/2} r_a^{-1/2} (\mathbb{F}_n^{(1)}(0, r_a s] - F^{(1)}(0, r_a s]) \right). \end{aligned}$$

Note that since F_1 is convex, $F_1(r_a s) \leq -F_1(-r_a)s$ for $-1 \leq s \leq 0$, and that $F_1(-r_a) \leq F_0(-r_a) + r_a \delta a \leq 2ar_a$. Furthermore, for $s \geq 0$, $F_1(r_a s) \geq 0$. This means that $\hat{f}(0) \geq f_1(0) + 2a$ implies that

$$\inf_{-1 \leq s \leq 0} \left(-n^{1/2} r_a^{-1/2} (\mathbb{F}_n^{(1)}(0, r_a s] - F^{(1)}(0, r_a s]) \right) \geq \inf_{s \geq 0} \left(Cs - n^{1/2} r_a^{-1/2} (\mathbb{F}_n^{(1)}(0, r_a s] - F^{(1)}(0, r_a s]) \right).$$

Since the left-derivative of $F^{(1)}$ in 0 equals $f_0(0) + o_p(1)$, we can proceed as in the proof of Theorem 6.1 to conclude that our rate γ_n satisfies the first requirement of the theorem.

Now we need to bound $\|P_1 - P_0\|_1$, where P_0 is the distribution of $(X_1, \dots, X_n)$ and P_1 the distribution of $(X_1^{(1)}, \dots, X_n^{(1)})$. We do this by bounding the Hellinger distance between f_0 and f_1 :

$$\begin{aligned}
H^2(f_0, f_1) &= \int_{-1}^0 \left(\sqrt{f_1(s)} - \sqrt{f_0(s)} \right)^2 ds \\
&= f_0(0) \int_{-1}^0 \left(\sqrt{\frac{f_1(s)}{f_0(0)}} - \sqrt{\frac{f_0(s)}{f_0(0)}} \right)^2 ds \\
&\leq \frac{1}{2} f_0(0) \int_{-1}^0 \frac{(f_1(s) - f_0(s))^2}{f_0(0)^2} ds \\
&\leq \frac{a^2 \delta^2 s_{\delta a} + \eta_a^2}{2 f_0(0)} \\
&\leq \frac{a^2 \delta^2 r_a}{f_0(0)}.
\end{aligned}$$

For the last inequality we use that for n big enough, $r_a < 1/2$. In the case where $b > a$, you could use the fact that for n big enough, $f_0(r_b) \geq f_0(0)/2$, to get the first inequality (with a different constant). It now follows that

$$\|P_1 - P_0\|_1 \leq 2\sqrt{H^2(p_1, p_0)} \leq 2\sqrt{n H^2(f_0, f_1)} \leq C\delta/\sqrt{f_0(0)}.$$

Choose $\delta \in (0, 1]$ small enough, such that $\|P_1 - P_0\| < 2 - 4\beta$, and follow the proof of Theorem 3.7. $\square$
